About this Manual

This manual describes how to get started using the DT-Open Layers for .NET Class Library to develop application programs for data acquisition devices that conform to the DT-Open Layers standard.

Intended Audience

This document is intended for engineers, scientists, technicians, OEMs, system integrators, or others responsible for developing application programs using Microsoft® Visual Studio .NET 2003 to 2012 to perform data acquisition operations.

It is assumed that you are a proficient programmer in Visual C# or Visual Basic .NET, and that you have familiarity with data acquisition principles and the requirements of your application.

What You Should Learn from this Manual

This manual provides installation instructions, summarizes the classes and members of the DT-Open Layers for .NET Class Library, and describes how to develop a data acquisition program using these classes. Using this manual, you should be able to successfully install the DT-Open Layers for .NET Class Library and get started writing a data acquisition application.

This manual is intended to be used with the online help for the DT-Open Layers for .NET Class Library, which is an integrated part of the software.

Note: This manual describes only those class members that are specific to the DT-Open Layers for .NET Class Library. Refer to your Microsoft Visual Studio .NET documentation for information about inherited classes and class members.

Organization of this Manual

This manual is organized as follows:

- **Chapter 1, “Getting Started,”** describes what you need to use the DT-Open Layers for .NET Class Library, how to install the software, how to access the online help, and how to use the example programs.

- **Chapter 2, “Library Summary,”** summarizes the classes, delegates, enumerations, and structures provided in the DT-Open Layers for .NET Class Library.

- **Chapter 3, “Using the OpenLayers.Base Namespace,”** describes how to use the OpenLayers.Base namespace to perform data acquisition operations on a DT-Open Layers-compliant device.
• Chapter 4, “Using the OpenLayers.DeviceCollection Namespace,” describes how to use the OpenLayers.DeviceCollection namespace to perform data acquisition operations on a DT-Open Layers-compliant device collection.

• Chapter 5, “Programming Flowcharts for the OpenLayers.Base Namespace,” provides programming flowcharts for using the properties, methods, and events that are provided in the OpenLayers.Base namespace of the DT-Open Layers for .NET Class Library.

• Chapter 6, “Programming Flowcharts for the OpenLayers.DeviceCollection Namespace,” provides programming flowcharts for using the properties, methods, and events that are provided in the OpenLayers.DeviceCollection namespace of the DT-Open Layers for .NET Class Library.

• Chapter 7, “Product Support,” describes how to get help if you have trouble using the DT-Open Layers for .NET Class Library.

• Appendix A, “Error Codes and Messages,” provides a list of error codes and descriptions that can be returned by the DT-Open Layers for .NET Class Library.

• An index completes this manual.

**Conventions Used in this Manual**

The following conventions are used in this manual:

• Notes provide useful information that requires special emphasis, cautions provide information to help you avoid losing data or damaging your equipment, and warnings provide information to help you avoid catastrophic damage to yourself or your equipment.

• Items that you select or type are shown in **bold**. Function names also appear in bold.

• Code fragments are shown in **courier font**.

• Methods and properties may be shown to indicate the class to which they belong, as follows: `DeviceMgr.Get` method means that this is the `Get` method of the `DeviceMgr` class. Similarly, `SubsystemBase.AnalogSubsystem.AnalogInputSubsystem.Start` means that this is the `Start` method of the `AnalogInputSubsystem` class, which is derived from the `AnalogSubsystem` class, which, in turn, is derived from the `SubsystemBase` class.

**Related Information**

Refer to the following documentation for more information on using the DT-Open Layers for .NET Class Library:

• DT-Open Layers for .NET Class Library Online Help. This help file is integrated as part of the software. Refer to page 23 for information on how to open this help file.

• Device-specific documentation. These manuals are provided on your Data Acquisition OMNI CD™ CD.

• Microsoft Visual Studio .NET documentation.
Where to Get Help

Should you run into problems installing or using the DT-Open Layers for .NET Class Library, our Technical Support Department is available to provide prompt, technical assistance. Refer to Chapter 7 for more information. If you are outside the U.S. or Canada, call your local distributor; see our web site (www.datatranslation.com) for the name and telephone number of your nearest distributor.

What’s Included

The following software is provided on the Data Acquisition OMNI CD for programming DT-Open Layers-compliant devices in Visual C# and Visual Basic .NET:

- DT-Open Layers for .NET Class Library – Provides properties, methods, and events for performing data acquisition operations. This library includes the OpenLayers.Base and OpenLayers.DeviceCollection namespaces.

- DT-Display for .NET Control – Provides a control for plotting data at high speed. You can use this control to plot data that was acquired from the DT-Open Layers for .NET Class Library. This control includes the OpenLayers.Controls and OpenLayers.Signals namespaces.

These assemblies are supported under Windows XP (32-bit), Windows Vista (32-bit and 64-bit), Windows 7 (32-bit and 64-bit), and Windows 8 (32-bit and 64-bit).

This document describes the DT-Open Layers for .NET Class Library. For more information on the DT-Display control, refer to the DT-Display for .NET User’s Manual on the CD.
What is the DT-Open Layers for .NET Class Library

The DT-Open Layers for .NET Class Library is a native .NET set of object-oriented classes for programming Data Translation's data acquisition devices in Visual C# and Visual Basic .NET.

The DT-Open Layers for .NET Class Library allows you to access the capabilities of your device programmatically. The library is fully compatible with the DT-Open Layers™ standard for developing integrated, modular application programs under Windows. Therefore, you can add support for a new data acquisition device at any time. Just add the new DT-Open Layers device driver, modify your code to incorporate the features of the new device, and then recompile the code. Any existing code remains unchanged.

**Note:** This library is not compatible with the DT-Open Layers Software Development Kit (SDK). Therefore, any existing programs written using the SDK must be modified to work with the DT-Open Layers for .NET Class Library.

The list of supported data acquisition devices is constantly expanding. For the most up-to-date information, refer to the Data Translation web site (www.datatranslation.com).

Device Collection Support in Open Layers

Some devices, such as the VIBbox system, are collection of other devices and subsystems that are connected together through the Sync Bus. For devices and subsystems that support expansion through the Sync Bus, you can use the DT Device Collection Manager application to combine the devices to appear as one collection.

Once a device collection is defined, you can use the OpenLayers.DeviceCollection namespace in the DT-Open Layers for .NET Class Library to perform analog input and/or analog output operations on the collection.

**Note:** Only subsystems that support expansion through the Sync Bus can be added to a collection. For most devices, this applies to the analog input subsystem only. However, some devices, such as the VIBbox and DT9857E module, support expansion of the analog input and analog output subsystems through the Sync Bus. The OpenLayers.DeviceCollection namespace supports only those subsystems that are added to the collection.
What You Need

To use the DT-Open Layers for .NET Class Library, ensure that your system meets the following minimum requirements:

- PC with a Pentium II 450 MHz minimum processor (Pentium II 600 MHz recommended)
- Microsoft® Windows® XP Professional, Windows XP Home Edition (does not support creating Web applications or XML Web servers in .NET Professional), Windows Vista®, Windows 7®, Windows 8, or Windows Server™ 2003
- Minimum RAM requirements depend on the operating system you are using; consult your operating system documentation for details
- Visual Studio .NET 2005 to 2012 and .NET Framework 2.0 to 4.5 for developing Windows 32-bit and 64-bit applications
- CD-ROM or DVD drive
- Super VGA (1024 x 768) or higher resolution display with 256 colors
- Microsoft mouse or compatible pointing device
- One or more of the supported Data Translation data acquisition devices

Installing the Software

**Note:** Ensure that you install Microsoft Visual Studio .NET before installing the DT-Open Layers for .NET Class Library.

The DT-Open Layers for .NET Class Library is installed automatically when you install the device driver for your device. Refer to your documentation for your device for more information.

If you are building 32-bit .NET applications (supported in Visual Studio .NET 2005 and higher), these assemblies are located in the following directory:

    Program Files\Data Translation\DotNet\OLClassLib\Framework 2.0 Assemblies

If you are building 64-bit .NET applications (supported in Visual Studio .NET 2005 and later), these assemblies are located in this directory:

    Program Files (x86)\Data Translation\DotNet\OLClassLib\Framework 2.0 Assemblies

You can determine how your application will run by configuring the build settings. For example, if you build your application with the "any CPU" build setting, your application will run as a 32-bit application on 32-bit systems or as a 64-bit application on 64-bit systems.
Using the Online Help

The online help for the DT-Open Layers for .NET Class Library is an integrated part of the software.

You can access the help file in one of the following ways:

- From the Task Bar, select Start | Programs | Data Translation, Inc | DT-Open Layers for .NET | DT-Open Layers Class Library | DT-Open Layers for .NET API Help. The stand-alone HTML help file is displayed. Click on OpenLayers.Base for help on the class library.

- Press F1 on any property or method of the class library for context-sensitive help.

The online help contains all of the specific reference information for each of the properties, methods, events, error codes, and so on, included in the DT-Open Layers for .NET Class Library.
Using the Example Programs

To help you understand more about using the classes included in the DT-Open Layers for .NET Class Library, the example programs, listed in Table 1, are provided.

For detailed information on the example programs, refer to the SamplesHelp help file provided with the DT-Open Layers for .NET Class Library.

## Analog Input (cont.)

ReadBufferedDataFromMultiSensor

For devices, such as the DT9829 module, that support multiple sensor types, configures the selected analog input channel for the appropriate sensor type, and uses continuous (post-trigger) mode and an internal clock to acquire multiple samples from an analog input channel. The data is returned in the engineering units for the specified sensor type. You can acquire data for a specified number of buffers and then stop (finite), or requeue the buffers to acquire data continuously (continuous).

## Analog Output

**WriteSingleValueAsVolts**
Writes a single voltage value to a single analog output channel.

**WriteSingleValueAsRaw**
Writes a single raw count value to a single analog output channel.

**WriteSingleValuesAsVolts**
For subsystems that support simultaneous operations, simultaneously writes single voltage values to four analog output channels.

**WriteSingleValueAsRaw_ProgRanges**
Writes a single value, represented as a raw count, to a single analog output channel, and demonstrates how to specify the voltage range for the subsystem.

**WriteBufferedDataAsVolts**
Uses continuous mode and an internal clock to write multiple values, represented as voltages, to the analog output channels. You can output three buffers of data and then stop (finite), or output data from the three buffers continuously (continuous).

## Digital Input

**ReadSingleValue**
Reads a single value from a digital input port.

**InterruptOnChange**
Reads data continuously from a digital input port, interrupting when a value of a digital input line changes state. The current value of the digital input port and the digital input lines that changed state are displayed.

## Digital Output

**WriteSingleValue**
Writes a single value to a digital output port.

**DT9871TempNET**
Supported on the DT9871 instrument only, configures the TEMPPoint instrument, acquires and displays data from up to 48 RTD or thermocouple input channels, optionally logs the acquired data to disk, reads the value of the digital input port, and updates the value of the digital output port. This application also allows you to set minimum and maximum threshold values for the analog input channels, and update the value of a digital output line when the threshold condition occurs.

To open and run these examples, do the following:

1. Start Microsoft Visual Studio .NET.
2. Click File, click Open, and then click Project.
3. Select the example you want to open from C:\Program Files\DataTranslation\DotNet\OLClassLib\Examples folder (if you installed the software using the default destination location).
4. From the main menu of Microsoft Visual Studio .NET, click Build, and then click Build Solution to build the project.

Note: These examples are provided as 32-bit applications. You can rebuild them as 64-bit applications, if desired, by referencing the x64 DT-Open Layers for .NET assembly (OpenLayers.Base.dll) located in Program Files (x86)\Data Translation\DotNet\OLClassLib\Framework 2.0 Assemblies (64-bit). Refer to page 23 for more information.

5. To run the example, click Debug from the main menu, and then click Start.
   The example program is now running.
6. Use the capabilities of the example program to see how it operates.
7. When you are finished using the example program, click Debug from the main menu, then click Stop Debugging.
8. View the user interface of the example program by clicking the appropriate [Design] tab on the main window.
9. View the source code for the example program by clicking the appropriate tab (such as example.cs) on the main window.
10. Repeat steps 2 through 9 for each example program you want to open, run, and view.
Creating Your Own Program

To create your own application program, do the following:

1. Start Microsoft Visual Studio .NET.

2. Click File, click New, and then click Project.

3. Select the language you want to develop in (Visual Basic Projects or Visual C# Projects), and the template that you want to use (such as, Windows Application).

4. Enter the project name and where you want to save your project, and then click OK. The design environment is shown.

5. From the Solution Explorer window, right-click References, and then click Add Reference (or from the Project Menu, select Add Reference). The Add Reference dialog box appears.

6. From the .NET tab, click OpenLayers for .NET, click Select, and then click OK. The OpenLayers.Base assembly is now referenced in your application.

7. If desired, click Object Browser from the main window, double-click openlayers.base, and then double-click OpenLayers.Base. All the classes included in the library are listed.

8. Select any of the classes to see its methods and properties.

9. Press F1 to access the context-sensitive online help for the library.

10. Develop your code, as appropriate, using the example programs and the information in this manual.

11. To build your program, click Build from the main menu, and then click Build Solution.

12. To run your program, click Debug from the main menu, and then click Start.

13. To save your program, click File, and then click Save All.

14. When you are finished, click File, and the click Close Solution before exiting from Microsoft Visual Studio .NET.
Distributing Your Program

When you distribute your program, ensure that you also distribute the version of the OpenLayers.Base assembly that was used to create your program. In addition, ensure that any Data Translation devices that are used by your program (along with their device drivers) are installed on the target machine.

One of the best ways to distribute your program is to create a Windows installation project that includes all the necessary files required to run your program. To create an installation project, do the following:

1. Open the program (solution) that you want to distribute within Visual Studio .NET.
2. From the File menu, select Add Project, and then select New Project. The Add New Project dialog box appears.
3. Select Setup and Deployment Projects, and select the Setup Wizard template.
4. Specify a name, such as Setup, for the installation project, specify the location for the installation project on your development system, and then click OK. The Welcome screen of the Setup wizard appears.
5. Click Next.
6. Select "Create a setup for a Windows application," and then click Next.
7. Select "Primary output from <the project to be distributed>," and then click Finish. Your program and the files OpenLayers.Base.dll and OpenLayers.Personality.dll are added to the Application Folder of the installation project automatically.
8. From the Solutions Explorer, right click on the installation project, and click Build.
9. To test that the setup program works properly, right click on the installation project, click Install, and follow the prompts.
10. Verify that your program and the files OpenLayers.Base.dll and OpenLayers.Personality.dll are installed in the directory that was specified by the setup program.
11. Distribute this setup program to your end users.

Overview

The DT-Open Layers for .NET Class Library consists of the OpenLayers.Base and OpenLayers.DeviceCollection namespaces. The OpenLayers.Base namespace provides the programming interface for all DT-Open Layers-compatible devices except device collections, which are programmed using the OpenLayers.DeviceCollection namespace.

The following elements comprise each namespace:

- **Classes** – Symbolic representations of objects. They define the operations that objects can perform using properties, methods, and events. In the DT-Open Layers for .NET Class Library, classes are used to define the I/O operations that can be performed on DT-Open Layers-compliant devices.

- **Delegates** – Data structures that refer to a static method. In the DT-Open Layers for .NET Class Library, delegates are used to call user-specified methods when specific events occur.

- **Enumerations** – Value types that associate names with specific values. In the DT-Open Layers for .NET Class Library, enumerations are used to define the values of properties and arguments used in methods.

- **Structures** – Value types that contain data members and functions like classes, but do not require heap allocation. In the DT-Open Layers for .NET Class Library, a structure is used to return specific information about DT-Open Layers devices.

This chapter summarizes the elements of the OpenLayers.Base and OpenLayers.DeviceCollection namespaces in the DT-Open Layers for .NET Class Library.
OpenLayers.Base Namespace

The OpenLayers.Base namespace provides the programming interface for DT-OpenLayers-compatible hardware devices. This is the interface to use for all DT-OpenLayers-compatible devices, except those devices that are defined as collections (such as the VIBbox system or a user-defined collection created using the DT Device Collection Manager application).

This section describes the elements of the OpenLayers.Base namespace. Refer to Chapter 3 for more information on how to use the OpenLayers.Base namespace.

Classes

The OpenLayers.Base namespace contains the classes listed in Table 2. Each class contains properties, methods, and/or events that allow you to perform specific operations. This section describes the classes and their members.

a. The AnalogSubsystem class provides the common properties, methods, and events for performing analog I/O operations. This is the base class for the analog input and analog output subsystems. This class inherits many of its capabilities from the SubsystemBase class. You cannot instantiate this object.

b. The SubsystemBase class provides the common properties, methods, and events that are inherited by the subsystems. This is the base class for all subsystems; you cannot instantiate this object.

c. The GeneralEventArgs class contains data that is returned by all DT-Open Layers events that are sent to the user.
Device Management

The OpenLayers.Base namespace provides the following classes for managing devices:

- DeviceMgr, described below
- Device, described starting on page 36
- SimultaneousStart, described starting on page 38

DeviceMgr Class

The DeviceMgr class provides methods for managing DT-Open Layers devices in the system and for assigning a Device object to each DT-Open Layers device that you want to use. Table 3 lists the methods in the DeviceMgr class.

Note: This class exposes the Device object.

Device Class

The Device class provides a constructor, properties, and methods for encapsulating an DT-Open Layers device and managing and distributing subsystems for the device.

To access a Device object, it is recommended that you use the DeviceMgr.GetDevice method. If you prefer, you can also get a Device object using the Device constructor of the Device class.

Note: This class exposes the following objects: SimultaneousStart, AnalogInputSubsystem, AnalogOutputSubsystem, DigitalInputSubsystem, DigitalOutputSubsystem, CounterTimerSubsystem, TachometerSubsystem, and QuadratureDecoderSubsystem.
Table 4 lists the members of the Device class.

SimultaneousStart Class

The SimultaneousStart class allows you to start multiple subsystems simultaneously using the properties listed in Table 5.

You access the SimultaneousStart object through the Device object.

Subsystem Operations

The following major classes are provided within the OpenLayers.Base namespace for performing subsystem operations:

- AnalogInputSubsystem, described below
- AnalogOutputSubsystem, described starting on page 47
- DigitalInputSubsystem, described starting on page 52
- DigitalOutputSubsystem, described starting on page 56
- CounterTimerSubsystem, described starting on page 60
- TachSubsystem, described starting on page 65
- QuadratureDecoderSubsystem, described starting on page 69

AnalogInputSubsystem Class

The AnalogInputSubsystem class encapsulates all methods, properties, and events that are specific to analog input operations. Table 6 lists the members of the AnalogInputSubsystem class.

To create an instance of this class, use the Device.AnalogInputSubsystem method (recommended) or the AnalogInputSubsystem constructor.
Note: This class provides interfaces to the following objects: BufferQueue, ChannelList, Clock, SupportedChannels, Trigger, and TriggeredScan.

This class inherits the members of the AnalogSubsystem and SubsystemBase classes.

For subsystems that support strain gages, acquires a single value from a full-bridge-based transducer and returns the value in the engineering units of the transducer.

For subsystems that support current measurement, acquires a single value from a current channel and returns the value in Amperes.

For subsystems that support bridges, acquires a single value from a general-purpose bridge or bridge-based sensor and returns the value in the volts.

Acquires a single value from an input channel and returns it in raw counts.

Acquires a single value from a resistance measurement channel and returns the resistance value in ohms.

Acquires a single value from an input channel and returns it in the engineering units for the specified sensor.

For subsystems that support strain gages, acquires a single value from an input channel and returns the value in microstrain.

Overloaded method. Acquires a single value from an input channel and returns it as a temperature value based on the specified thermocouple or RTD type and temperature units.

Acquires a single value from an input channel and returns the data in voltage.

For subsystems that support current measurement and simultaneous operations, simultaneously acquires a single value from each current channel and returns the value in Amperes.

For subsystems that support simultaneous operations, simultaneously acquires a single value from each input channel and returns the data in raw counts.

For subsystems that support simultaneous operations, simultaneously acquires a single value from each input channel and returns the values in the engineering units of the specified sensor.

For subsystems that support simultaneous operations, thermocouples or RTDs, and the ability to return floating-point values, simultaneously acquires a single temperature value from each input channel and returns the data, in the units you specify, as an array of floating-point values.

AnalogOutputSubsystem Class

The AnalogOutputSubsystem class encapsulates all methods, properties, and events that are specific to analog output operations. Table 7 lists the members of the AnalogOutputSubsystem class.

To create an instance of this class, use the Device.AnalogOutputSubsystem method (recommended) or the AnalogOutputSubsystem constructor.

**Note:** This class provides interfaces to the following objects: BufferQueue, ChannelList, Clock, SupportedChannels, and Trigger.

This class inherits the members of the AnalogSubsystem and SubsystemBase classes.

The TachSubsystem class encapsulates all methods, properties, and events that are specific to tachometer operations. Table 10 lists the members of the TachSubsystem class.

To create an instance of this class, use the Device.TachSubsystem method (recommended) or the TachSubsystem constructor.

Note: This class provides interfaces to the BufferQueue, ChannelList, Clock, SupportedChannels, and Trigger objects; for most DT-Open Layers devices, these objects are not supported for tachometer operations.

This class inherits the members of the SubsystemBase class.

Channels

The following classes are provided within the OpenLayers.Base namespace for dealing with channels in a continuous I/O operation:

- SupportedChannelInfo, described below
- SupportedChannels, described starting on page 76
- ChannelListEntry, described starting on page 76
- ChannelList, described starting on page 77
- StrainGageTeds class, described starting on page 78
- BridgeSensorTeds class, described starting on page 80

SupportedChannelInfo Class

When you get a subsystem of a specified type, the software automatically populates the properties of the SupportedChannelInfo class, listed in Table 13, for each channel.

To access a SupportedChannelInfo object, use the SupportedChannels class, described on page 76.

A ChannelList object is accessible using any subsystem object whose SupportsContinuous property returns True. The following classes expose an interface to the ChannelList object:

- AnalogInputSubsystem, described on page 38
- AnalogOutputSubsystem, described on page 47
- DigitalInputSubsystem, described on page 52
- DigitalOutputSubsystem, described on page 56
- CounterTimerSubsystem, described on page 60
StrainGageTeds Class

The StrainGageTeds class encapsulates all properties and methods that are specific to analog input channels that support TEDS (Transducer Electronic Data Sheet) for strain gages. Table 6 lists the members of the StrainGageTeds class.

</tr>
</tbody>
</table>
You can access a Clock object through the following classes:

- AnalogInputSubsystem, described on page 38
- AnalogOutputSubsystem, described on page 47
- DigitalInputSubsystem, described on page 52
- DigitalOutputSubsystem, described on page 56
- CounterTimerSubsystem, described on page 60
- TachSubsystem, described on page 65
- QuadratureDecoderSubsystem, described on page 69

**Triggers**

The following classes are provided for controlling how a subsystem is triggered:

- Trigger, described below
- Reference trigger, described on page 84
- TriggeredScan, described on page 85

**Trigger Class**

The Trigger class provides the properties listed in Table 20 for controlling the trigger of a subsystem. For devices that support a start trigger and a reference trigger, the Trigger class is used to set up the start trigger, which starts pre-trigger data acquisition.
You can access a Trigger object through the following classes:

- AnalogInputSubsystem, described on page 38
- AnalogOutputSubsystem, described on page 47
- DigitalInputSubsystem, described on page 52
- DigitalOutputSubsystem, described on page 56
CounterTimerSubsystem, described on page 60
TachSubsystem, described on page 65
QuadratureDecoderSubsystem, described on page 69

ReferenceTrigger Class

The ReferenceTrigger class provides the properties listed in Table 21 for controlling the reference trigger of a subsystem. For devices that support a reference trigger, pre-trigger data acquisition stops and post-trigger acquisition starts when the reference trigger event occurs. Post-trigger acquisition stops when the number of samples you specify for the post-trigger scan count has been reached.

You can access a ReferenceTrigger object through the following classes:

- AnalogInputSubsystem, described on page 38
- AnalogOutputSubsystem, described on page 47
- DigitalInputSubsystem, described on page 52
- DigitalOutputSubsystem, described on page 56
- CounterTimerSubsystem, described on page 60
- TachSubsystem, described on page 65
- QuadratureDecoderSubsystem, described on page 69

**TriggeredScan Class**

The TriggeredScan class allows you to scan the entries in a ChannelList object a specified number of times when the device detects a specified retrigger source by using the properties listed in Table 22.

You can access the TriggeredScan object through the AnalogInputSubsystem class.

BufferQueue Class

The BufferQueue class provides the properties and methods listed in Table 25 for managing a queue of OlBuffer objects for a continuous I/O operation.

<table>

</tr>
<tr>
<td></td>
<td>Reallocate</td>
<td>Reallocates the OlBuffer object to the specified number of samples. The existing internal data buffer is deallocated and any data that it contained is lost.</td>
</tr>
</tbody>
</table>

Table 25: Members of the BufferQueue Class

You can access a BufferQueue object through the following classes:

- AnalogInputSubsystem, described on page 38
- AnalogOutputSubsystem, described on page 47
- DigitalInputSubsystem, described on page 52
- DigitalOutputSubsystem, described on page 56
- CounterTimerSubsystem, described on page 60
- TachSubsystem, described on page 65
- QuadratureDecoderSubsystem, described on page 69
Event Handling

The following classes are provided for handling events raised by the OpenLayers.Base namespace:

- GeneralEventArgs, described on page 90
- BufferDoneEventArgs, described on page 90
- DriverRunTimeErrorEventArgs, described on page 90
- EventDoneEventArgs, described on page 91
- InterruptOnChangeEventArgs, described on page 91
- IOCompleteEventArgs, described on page 91
- MeasureDoneEventArgs, described on page 92

GeneralEventArgs

The GeneralEventArgs class provides the properties listed in Table 26 to return information about DT-Open Layers events. This object is generated internally and is returned to event delegates. Refer to page 94 for more information on delegates.

<table>
<thead>
<tr>
<th>Member Type</th>
<th>Member Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Read-Only Properties</td>
<td>DateTime</td>
<td>Returns the time stamp of when the associated event occurred.</td>
</tr>
<tr>
<td></td>
<td>Subsystem</td>
<td>Returns the subsystem (AnalogInput, AnalogOutput, DigitalInput, DigitalOutput, CounterTimer, Tachometer, or QuadratureDecoder) that raised the event.</td>
</tr>
</tbody>
</table>

BufferDoneEventArgs

The BufferDoneEventArgs class inherits the members of the GeneralEventArgs class and adds the OlBuffer property. When the BufferDoneEvent event is raised, the completed buffer is returned in the OlBuffer property.

This object is generated internally and returned to the BufferDoneHandler delegate. Refer to page 94 for more information on delegates.

DriverRunTimeErrorEventArgs

The DriverRunTimeErrorEventArgs class inherits the members of the GeneralEventArgs class and adds the properties listed in Table 27 to return data related to the event DriverRunTimeErrorEvent.

This object is generated internally and returned to the DriverRunTimeErrorEventHandler delegate. Refer to page 94 for more information on delegates.
EventDoneEventArgs

The EventDoneEventArgs class inherits the members of the GeneralEventArgs class and adds the `Data` property. When the EventDoneEvent event is raised, the `Data` property returns the data associated with the event. The meaning of the data depends on the device and subsystem used. Refer to your device documentation for details.

This object is generated internally and returned to the `EventDoneHandler` delegate. Refer to page 94 for more information on delegates.

InterruptOnChangeEventArgs

The InterruptOnChangeEventArgs class inherits the members of the GeneralEventArgs class and adds the properties listed in Table 28 to return data related to the event `InterruptOnChangeEvent`.

This object is generated internally and returned to the `InterruptOnChangeHandler` delegate. Refer to page 94 for more information on delegates.

</tr>
<tr>
<td></td>
<td>Message</td>
<td>Returns a descriptive string associated with the error code. Refer to Appendix A for more information.</td>
</tr>
</tbody>
</table>

IOCompleteEventArgs

The IOCompleteEventArgs class inherits the members of the GeneralEventArgs class and adds the properties listed in Table 29 to return data related to the event IOCompleteEvent.

This object is generated internally and returned to the `IOCompleteHandler` delegate. Refer to page 94 for more information on delegates.
The MeasureDoneEventArgs class inherits the members of the GeneralEventArgs class and adds the Count property to return the data related to the event MeasureDoneEvent. The Count is the number of internal clock ticks that were counted during the measurement period. This object is generated internally and returned to the MeasureDoneHandler delegate. Refer to page 94 for more information on delegates.

### Error Handling

The following classes are provided for handling errors that may occur in the OpenLayers.Base namespace:

- OlException, described below
- OlError, described on page 93

#### OlException

The OlException class provides the properties listed in Table 30 for dealing with errors that can be generated by the library.
The OlError class provides the OlError constructor for encapsulating an DT-Open Layers error code. The OlError class provides the methods listed in Table 31 for getting information about errors returned by the DT-Open Layers for .NET Class Library. Refer to Appendix A for a list of errors that may be returned by the DT-Open Layers for .NET Class Library.

Structures

The OpenLayers.Base namespace provides the following structures:

- **HardwareInfo** structure – This structure is used by the Device.GetHardwareInfo method to return information about a DT-Open Layers-compliant device.

  Table 35 lists the fields that are contained in the HardwareInfo structure.

OpenLayers.DeviceCollection Namespace

The OpenLayers.DeviceCollection namespace provides the programming interface for DT-Open Layers-compatible device collections. This is the interface to use for devices that are defined as collections, such as the VIBbox system or a user-defined collection created using the DT Device Collection Manager application. (For all other DT-Open Layers-compatible devices, use the OpenLayers.Base namespace instead.)

Devices in a collection are connected together through the Sync Bus. Only subsystems, such as the analog input and possibly the analog output subsystem, are supported in the collection as these are the only subsystems that may provide expansion through the Sync Bus. Check your hardware documentation to determine which subsystems are supported in the collection.

This section describes the elements of the OpenLayers.DeviceCollection namespace. Refer to Chapter 4 for more information on how to use the OpenLayers.DeviceCollection namespace.

Classes

The OpenLayers.DeviceCollection namespace contains the classes listed in Table 38. Each class contains properties, methods, and/or events that allow you to perform specific operations. This section describes the classes and their members.

a. The AnalogSubsystem class provides the common properties, methods, and events for performing analog I/O operations. This is the base class for the analog input and analog output subsystems. This class inherits many of its capabilities from the SubsystemBase class. You cannot instantiate this object.

b. The SubsystemBase class provides the common properties, methods, and events that are inherited by the subsystems. This is the base class for all subsystems; you cannot instantiate this object.

c. The GeneralEventArgs class contains data that is returned by all DT-Open Layers events that are sent to the user.
Device Management

The OpenLayers.DeviceCollection namespace provides the following classes for managing devices:

- DeviceMgr, described below
- Device, described starting on page 110
- SimultaneousStart, described starting on page 111

DeviceMgr Class

The DeviceMgr class provides methods for managing DT-Open Layers devices in the system and for assigning a Device object to each DT-Open Layers device that you want to use. Table 39 lists the methods in the DeviceMgr class.

Note: This class exposes the Device object.

<table>

</tr>
<tr>
<td></td>

</tr>
</tbody>
</table>

Device Class

The Device class provides a constructor, properties, and methods for encapsulating an DT-Open Layers device and managing and distributing subsystems for the device.

To access a Device object, it is recommended that you use the DeviceMgr.GetDevice method. If you prefer, you can also get a Device object using the Device constructor of the Device class.

Note: This class exposes the AnalogInputSubsystem, AnalogOutputSubsystem, and SimultaneousStart objects.
Table 40 lists the members of the Device class.

Subsystem Operations

The following major classes are provided within the OpenLayers.DeviceCollection namespace for performing subsystem operations:

- AnalogInputSubsystem, described below
- AnalogOutputSubsystem, described starting on page 117

AnalogInputSubsystem Class

The AnalogInputSubsystem class encapsulates all methods, properties, and events that are specific to analog input operations. Table 42 lists the members of the AnalogInputSubsystem class.

To create an instance of this class, use the Device.AnalogInputSubsystem method (recommended) or the AnalogInputSubsystem constructor.

**Note:** This class provides interfaces to the following objects: BufferQueue, ChannelList, Clock, SupportedChannels, and Trigger.

This class inherits the members of the AnalogSubsystem and SubsystemBase classes.

The AnalogOutputSubsystem class encapsulates all methods, properties, and events that are specific to analog output operations. Table 43 lists the members of the AnalogOutputSubsystem class.

To create an instance of this class, use the `Device.AnalogOutputSubsystem` method (recommended) or the AnalogOutputSubsystem constructor.

**Note:** This class provides interfaces to the following objects: BufferQueue, ChannelList, Clock, SupportedChannels, and Trigger.

This class inherits the members of the AnalogSubsystem and SubsystemBase classes.

Chapter 2

Channels

The following classes are provided within the OpenLayers.DeviceCollection namespace for dealing with channels in a continuous I/O operation:

- SupportedChannelInfo, described below
- SupportedChannels, described starting on page 123
- ChannelListEntry, described starting on page 124
- ChannelList, described starting on page 124

SupportedChannelInfo Class

When you get a subsystem of a specified type, the software automatically populates the properties of the SupportedChannelInfo class, listed in Table 44, for each channel.

To access a SupportedChannelInfo object, use the SupportedChannels class, described on page 123.

Table 44: Members of the SupportedChannelInfo Class

</table>

You can access a SupportedChannels object through the following classes:

- AnalogInputSubsystem, described on page 112
- AnalogOutputSubsystem, described on page 117
ChannelListEntry Class

The ChannelListEntry class provides the constructor and properties listed in Table 46 to encapsulate a channel entry for a channel list of a specified subsystem.

</tbody>
</table>

ChannelList Class

The ChannelList class provides the properties and methods listed in Table 47 to create and manage a channel list, which is a collection of ChannelListEntry objects, for use in a continuous I/O operation.

Table 47: Members of the ChannelList Class

<table>

</table>
A ChannelList object is accessible using any subsystem object whose `SupportsContinuous` property returns True. The following classes expose an interface to the ChannelList object:

- AnalogInputSubsystem, described on page 112
- AnalogOutputSubsystem, described on page 117

**Clock Class**

The Clock class provides the properties and methods listed in Table 48 for controlling the clock of a specified subsystem.

</table>
You can access a Clock object through the following classes:

- AnalogInputSubsystem, described on page 112
- AnalogOutputSubsystem, described on page 117

**Triggers**

The following classes are provided for controlling how a subsystem is triggered:

- Trigger, described below
- Reference trigger, described on page 84

**Trigger Class**

The Trigger class provides the properties listed in Table 49 for controlling the trigger of a subsystem. For devices that support a start trigger and a reference trigger, the Trigger class is used to set up the start trigger, which starts pre-trigger data acquisition.

You can access a Trigger object through the following classes:

- AnalogInputSubsystem, described on page 112
- AnalogOutputSubsystem, described on page 117

**ReferenceTrigger Class**

The ReferenceTrigger class provides the properties listed in Table 50 for controlling the reference trigger of a subsystem. For devices that support a reference trigger, pre-trigger data acquisition stops and post-trigger acquisition starts when the reference trigger event occurs. Post-trigger acquisition stops when the number of samples you specify for the post-trigger scan count has been reached.

Buffer Management

The following classes are provided for managing buffers in continuous I/O operations:
- OlBuffer, described below
- BufferQueue, described on page 131

OlBuffer Class

The OlBuffer class provides the constructor, properties, and methods listed in Table 52 for encapsulating a data buffer that is used in a continuous I/O operation.

</table>

You can access a BufferQueue object through the following classes:

- AnalogInputSubsystem, described on page 112
- AnalogOutputSubsystem, described on page 117

Event Handling

The following classes are provided for handling events raised by the OpenLayers.DeviceCollection namespace:

- GeneralEventArgs, described on page 131
- BufferDoneEventArgs, described on page 132
- DriverRunTimeErrorEventArgs, described on page 132
- IOCompleteEventArgs, described on page 132

GeneralEventArgs

The GeneralEventArgs class provides the properties listed in Table 54 to return information about DT-Open Layers events. This object is generated internally and is returned to event delegates. Refer to page 134 for more information on delegates.
BufferDoneEventArgs

The BufferDoneEventArgs class inherits the members of the GeneralEventArgs class and adds the `OlBuffer` property. When the BufferDoneEvent event is raised, the completed buffer is returned in the `OlBuffer` property.

This object is generated internally and returned to the `BufferDoneHandler` delegate. Refer to page 134 for more information on delegates.

DriverRunTimeErrorEventArgs

The DriverRunTimeErrorEventArgs class inherits the members of the GeneralEventArgs class and adds the properties listed in Table 55 to return data related to the event DriverRunTimeErrorEvent.

This object is generated internally and returned to the `DriverRunTimeErrorEventHandler` delegate. Refer to page 134 for more information on delegates.

IOCompleteEventArgs

The IOCompleteEventArgs class inherits the members of the GeneralEventArgs class and adds the properties listed in Table 56 to return data related to the event IOCompleteEvent.

This object is generated internally and returned to the `IOCompleteHandler` delegate. Refer to page 134 for more information on delegates.
Error Handling

The following classes are provided for handling errors that may occur in the OpenLayers.Base namespace:

- OlException, described below
- OlError, described on page 134

### OlException

The OlException class provides the properties listed in Table 57 for dealing with errors that can be generated by the OpenLayers.DeviceCollection namespace.

You can subtract the value of the <code>AnalogInputSubsystem.ReferenceTrigger.PostTriggerScanCount</code> property, described on page 322, from the value of this property to determine when the reference trigger occurred and the number of pre-trigger samples that were acquired. For example, if the value of this property is 100, and you specified a value of 75 for the post-trigger scan count, you can determine that the reference trigger occurred at sample count 25 (100-75) of the last buffer; samples 25 through 99 are post-trigger samples and samples 0 to 24 are pre-trigger samples.</td>

OlError

The OlError class provides the OlError constructor for encapsulating an DT-Open Layers error code. The OlError class provides the methods listed in Table 58 for getting information about errors returned by the DT-Open Layers for .NET Class Library. Refer to Appendix A for a list of errors that may be returned by the DT-Open Layers for .NET Class Library.

Structures

The OpenLayers.DeviceCollection namespace provides the following structures:

- **HardwareInfo** structure – This structure is used by the `Device.GetHardwareInfo` method to return information about a DT-Open Layers-compliant device.

  Table 35 lists the fields that are contained in the `HardwareInfo` structure.

- **SingleValuesInfoRaw** structure – Used with the `SetSingleValuesAsRaw` method, specifies the analog output channel to update and the raw count to output on that channel.

  Table 62 lists the fields that are contained in the `SingleValuesInfoRaw` structure.
**SingleValuesInfoVolts** structure – Used with the `SetSingleValuesAsVolts` method, specifies the analog output channel to update and the voltage value to output on that channel.

Table 63 lists the fields that are contained in the `SingleValuesInfoVolts` structure.

Overview

To perform a data acquisition operation on a DT-Open Layers-compliant device, you need to do the following:

1. Import the namespace into your program.
2. Get a DeviceMgr object to manage DT-Open Layers devices.
3. Get a Device object for each DT-Open Layers device that you want to use.
4. Get a subsystem of each type that you want to use.
5. Determine what channels are supported on each subsystem, and set up channel parameters.
6. Set up and configure the subsystem.
7. Perform the I/O operations.
8. Start subsystems simultaneously, if supported.
9. Auto-calibrate the subsystem, if supported.
10. Handle events.
11. Handle errors.
12. When finished, clean up the memory and resources used by the operations.

The remaining sections in this chapter describe these steps in detail.
Importing the Namespace for the Library

To use any of the classes in the OpenLayers.Base namespace, you first need to import the namespace into your program, as follows:

**Visual C#**
using OpenLayers.Base

**Visual Basic**
Imports OpenLayers.Base
Getting a DeviceMgr Object

Before performing any operation using the OpenLayers.Base namespace, you must first use the DeviceMgr.Get method to return a DeviceMgr object. The DeviceMgr object is responsible for managing all DT-Open Layers devices in your system.

The following examples shows how to get a DeviceMgr object:

**Visual C#**

```csharp
DeviceMgr deviceMgr = DeviceMgr.Get();
```

**Visual Basic**

```vbnet
deviceMgr As DeviceMgr = DeviceMgr.Get()
```
Getting a Device Object

Once you have a DeviceMgr object, use the DeviceMgr.GetDevice method to return a Device object for each DT-Open Layers device that you want to use.

Note: If you wish, you can also create a Device object using the Device constructor instead of using the GetDevice method.

The following examples shows how to get a Device object for the device named deviceName:

**Visual C#**

Device device = deviceMgr.GetDevice (deviceName);

**Visual Basic**

device As Device = deviceMgr.GetDevice(deviceName)

You can determine if a DT-Open Layers-compatible device is plugged into your system by using the DeviceMgr.HardwareAvailable method. If this method returns True, at least one DT-Open Layers-compatible device is plugged into your system.

To determine the names of all DT-Open Layers-compatible devices plugged into your system, use the DeviceMgr.GetDeviceNames method.

You can also use the use the following properties and/or methods to return information about the specified Device object:

- **Device.BoardModelName** property – Returns the model name of the device.
- **Device.DeviceName** property – Returns the user-defined name for the device. You can modify this name using the DT-Open Layers Control Panel applet.
- **Device.DriverName** property – Returns the name of the Windows device driver for the device.
- **Device.DriverVersion** property – Returns the version of the Windows device driver for the device.
- **Device.GetHardwareinfo** method – Returns the driver id, product id, board id, and vendor id for the specified device. See page 106 for more information on these fields.

**Getting a Subsystem**

The following subsystem types are defined in the OpenLayers.Base namespace:

- **AnalogInputSubsystem** – This subsystem type represents the analog input channels of your device, if supported. Use this subsystem type if you want to acquire data from the analog input channels.

  If your device supports streaming digital input, counter/timer, and or quadrature decoder data through the analog input subsystem, use AnalogInputSubsystem to read this data.

- **AnalogOutputSubsystem** – This subsystem type represents the analog output channels of your device, if supported. Use this subsystem type if you want to update the values of the analog output channels.

  If your device supports streaming digital output data through the analog output subsystem, use AnalogOutputSubsystem to update the data on the digital output ports.

- **DigitalInputSubsystem** – This subsystem type represents the digital input lines of your device, if supported. Use this subsystem type if you want to read the values of the digital input lines on your device.

  If your device supports it, you can also use DigitalInputSubsystem to generate an interrupt when a digital input line changes state.

- **DigitalOutputSubsystem** – This subsystem type represents the digital output lines of your device, if supported. Use this subsystem type if you want to update the values the digital output lines.

- **CounterTimerSubsystem** – This subsystem type represents the counter/timer channels of your device, if supported. Use this subsystem type if you want to read the value of counter or output pulses from the counter under various conditions.

- **TachSubsystem** – This subsystem type represents the tachometer input channels of your device, if supported. Use this subsystem type if you want to read the value of a tachometer measurement.

- **QuadratureDecoderSubsystem** – This subsystem type represents the quadrature decoder channels of your device, if supported. Use this subsystem type if you want to perform quadrature decoder operations.

Your device may support all or a subset of these functions or subsystem types. In addition, your device may support multiple instances, called elements, of the same subsystem type. Element numbering is zero-based; that is, the first instance of the subsystem is called element 0, the second instance of the subsystem is called element 1, and so on. For example, if your device has two digital input ports, two subsystems of type DigitalInputSubsystem are available, differentiated as elements 0 and 1.
Once you have a Device object, you need to get a subsystem of the appropriate type for each subsystem element that you want to use. While you can do this using the constructor provided in each subsystem class, it is recommended that you use one of the following methods of the Device class:

- **Device.AnalogInputSubsystem** method – Returns an analog input subsystem for a specified element and Device object. Most DT-Open Layers devices group all the analog input channels into one analog input subsystem element (0). However, some devices, like the DT9820 Series, provide one element per A/D converter.

  The following example shows how to get an AnalogInputSubsystem object for element 0:

  **Visual C#**
  ```csharp
  AnalogInputSubsystem ainSS = device.AnalogInputSubsystem (0);
  ```

  **Visual Basic**
  ```vbnet
  ainSS As AnalogInputSubsystem = device.AnalogInputSubsystem(0)
  ```

- **Device.AnalogOutputSubsystem** method – Returns an analog output subsystem for a specified element and Device object. Most DT-Open Layers devices group all the analog output channels into one analog output subsystem element (0). The following example shows how to get an AnalogOutputSubsystem object for element 0:

  **Visual C#**
  ```csharp
  AnalogOutputSubsystem aoutSS = device.AnalogOutputSubsystem (0);
  ```

  **Visual Basic**
  ```vbnet
  aoutSS As AnalogOutputSubsystem = device.AnalogOutputSubsystem(0)
  ```

- **Device.DigitalInputSubsystem** method – Returns a digital input subsystem for a specified element and Device object. Most DT-Open Layers devices provide one digital input subsystem element for each digital input port. The following example shows how to get a DigitalInputSubsystem object for element 0:

  **Visual C#**
  ```csharp
  DigitalInputSubsystem dinSS = device.DigitalInputSubsystem (0);
  ```

  **Visual Basic**
  ```vbnet
  dinSS As DigitalInputSubsystem = device.DigitalInputSubsystem(0)
  ```

- **Device.DigitalOutputSubsystem** method – Returns a digital output subsystem for a specified element and Device object. Most DT-Open Layers devices provide one digital output subsystem element for each digital output port. The following example shows how to get a DigitalOutputSubsystem object for element 0:

  **Visual C#**
  ```csharp
  DigitalOutputSubsystem doutSS = device.DigitalOutputSubsystem (0);
  ```

  **Visual Basic**
  ```vbnet
  doutSS As DigitalOutputSubsystem = device.DigitalOutputSubsystem(0)
  ```
• **Device.CounterTimerSubsystem** method – Returns a counter/timer subsystem for a specified element and Device object. Most DT-Open Layers devices provide one counter/timer subsystem element for each counter/timer channel. The following example shows how to get a CounterTimerSubsystem object for element 0:

**Visual C#**

```csharp
CounterTimerSubsystem ctSS = device.CounterTimerSubsystem(0);
```

**Visual Basic**

```vbnet
ctSS As CounterTimerSubsystem = device.CounterTimerSubsystem(0)
```

• **Device.TachSubsystem** method – Returns a tachometer subsystem for a specified element and Device object. Most DT-Open Layers devices provide one tachometer subsystem element for each tachometer input channel. The following example shows how to get a TachSubsystem object for element 0:

**Visual C#**

```csharp
TachSubsystem tachSS = device.TachSubsystem(0);
```

**Visual Basic**

```vbnet
tachSS As TachSubsystem = device.TachSubsystem(0)
```

• **Device.QuadratureDecoderSubsystem** method – Returns a quadrature decoder subsystem for a specified element and Device object. Most DT-Open Layers devices provide one quadrature decoder subsystem element for each quadrature decoder channel. The following example shows how to get a QuadratureDecoderSubsystem object for element 0:

**Visual C#**

```csharp
QuadratureDecoderSubsystem quadSS = device.QuadratureDecoderSubsystem(0);
```

**Visual Basic**

```vbnet
quadSS As QuadratureDecoderSubsystem = device.QuadratureDecoderSubsystem(0)
```

You can determine the type of a specified subsystem by using the `SubsystemType` property within the appropriate subsystem class.

To return the number of elements supported by a specified subsystem type on a specified device, use the `Device.GetNumSubsystemElements` method.

You can determine the state of a subsystem using the `State` property within the appropriate subsystem class. The following states have been defined:

- **Initialized** – The subsystem has been initialized, but not configured.
- **ConfiguredForSingleValue** – The subsystem has been configured for a single-value operation.
- **ConfiguredForContinuous** – The subsystem has been configured for a continuous operation.
- Running – The subsystem is running.

**Note:** You can also use the **IsRunning** property within the appropriate subsystem class to determine if the subsystem is running.

- Stopping – The operation on the subsystem is in the process of stopping.
- Aborting – The operation on the subsystem is in the process of being aborted.
- Prestarted – The subsystem has been prestarted for a continuous simultaneous operation.
- IOComplete – For analog input subsystems, the final post-trigger samples has been copied to the user buffer. For analog output subsystems, the final analog output sample has been written from the FIFO on the device; this is a transient state, which may not be seen, but does occur.
Determining the Available Channels and Setting up Channel Parameters

When you get a subsystem of a specified type, the software automatically determines the number of available channels for the subsystem and creates a SupportedChannelInfo object for each channel. The SupportedChannelInfo object contains the following information:

- physical channel number
- logical channel number
- logical channel word
- channel name
- I/O type
- Information that pertains to voltage input channels:
  - termination resistor
  - sensor gain
  - sensor offset
- Information that pertains to thermocouple channels:
  - thermocouple type
  - CJC channel
- Information that pertains to RTD channels:
  - RTD type
  - resistor value (R0) for an RTD
  - coefficient A value for an RTD
  - coefficient B value for an RTD
  - coefficient C value for an RTD
  - sensor wiring configuration
- Information that pertains to thermistor channels:
  - coefficient A value for a thermistor
  - coefficient B value for a thermistor
  - coefficient C value for a thermistor
  - sensor wiring configuration
- Information that pertains to resistance measurement channels:
  - sensor wiring configuration
  - excitation current source
  - value for the internal excitation current source
• Information that pertains to accelerometer (IEPE) channels:
  − coupling
  − excitation current source
  − value for the internal excitation current source

• Information that pertains to bridge-based sensors:
  − bridge configuration
  − bridge transducer capacity
  − bridge transducer rated output
  − strain gage lead wire resistance
  − strain gage nominal resistance
  − strain gage offset nulling value in volts
  − strain gage shunt calibration resistor (enabled or disabled)
  − strain gage shunt calibration value

• Information that pertains to strain gage channels:
  − strain gage bridge configuration
  − strain gage poisson ratio
  − strain gage lead wire resistance
  − strain gage gage factor
  − strain gage nominal resistance
  − strain gage offset nulling value in volts
  − strain gage shunt calibration resistor (enabled or disabled)
  − strain gage shunt calibration value

To get a collection of SupportedChannelInfo objects, use the SupportedChannels class.

You can get the SupportedChannelInfo object for a specific channel using the SupportedChannels.GetChannelInfo method and any one of the following arguments:

• The physical channel number.
• The user-defined name of the channel.
• The subsystem type and logical channel number.
• The subsystem type, logical channel number, and logical channel word.

You can also use the SupportedChannels.Item ([ ]) property to return the SupportedChannelsInfo object at a specific index.

The following subsections describe the elements of the SupportedChannelsInfo class in more detail.
Physical and Logical Channels

The logical channel number, which is zero-based, maps the physical channel to the channel’s subsystem type. If the channels are native to the AnalogInputSubsystem, the logical channel number is the same as the physical channel number. If channels from other subsystem types are accessible through the AnalogInputSubsystem, the logical channel numbers are not the same as the physical channel numbers for the non-native channels.

For example, in Table 64, the SupportedChannels object for the analog input subsystem contains 8 analog input channels, four digital input ports, and two 32-bit counter/timers. As you can see, physical channels 0 to 7 map to logical channels 0 to 7 of the analog input subsystem, physical channels 8 to 11 map to logical channels 0 to 3 of the digital input subsystem, and physical channels 12 to 15 map to logical channels 0 and 1 of the counter/timer subsystem (in this case, since each counter is 32-bits, one logical channel maps to two 16-bit physical channels).

You can determine the number of a physical channel for a given subsystem using the SupportedChannelInfo.PhysicalChannelNumber property.
You can determine the number of a logical channels for a given subsystem using the `SupportedChannelInfo.LogicalChannelNumber` property.

To reference a channel by number, specify either the physical channel number or the subsystem type and logical channel number.

**Logical Channel Word**

For channels like 32-bit counter/timers that return multi-word data, the logical channel word, which is zero-based, maps the physical channel to the data word that it returns. For example, looking at the counter/timer subsystem type in Table 65, physical channel 12 has a logical channel word of 0, indicating that this channel returns the first 16-bits of data. Physical channel 13 has a logical channel word of 1, indicating that this channel returns the second 16-bits of data.

For channels that do not return multi-word data, the value of the logical channel word is -1.

You can determine the value of the logical channel word for a given channel using the `SupportedChannelInfo.LogicalChannelWord` property.

To reference a channel by logical channel word, specify the subsystem type, logical channel number, and logical channel word.

**Channel Name**

By default, each channel that is listed in the `SupportedChannelInfo` class has a name that describes the subsystem type and includes the logical channel number and logical channel word, if applicable. Examples of default names include `Ain0` for analog input channel 0, `Aout1` for analog output channel 1, `Din0` for digital input channel 0, `Dout2` for digital output channel 2, `CT0 Word 1` for counter/timer channel 0 (word 1), and `Quad1 Word 0` for quadrature decoder channel 1 (word 0).

You can specify your own name for a channel using the `SupportedChannelInfo.Name` property.

To reference a channel by name, specify the name of the channel.

**IOType**

You can determine what kind of I/O operation is supported for a particular channel of a given subsystem using the `SupportedChannelInfo.IOType` property.

This property returns one of the following I/O types:

- **VoltageIn** – Refer to page 155 for information on setting up additional parameters for this channel I/O type.
- **VoltageOut**
- **DigitalInput**
- **DigitalOutput**
- **QuadratureDecoder**
- **CounterTimer**
- **Tachometer**
- **Current** – Refer to page 157 for information on setting up additional parameters for this channel I/O type.
- **Thermocouple** – Refer to page 157 for information on setting up additional parameters for this channel I/O type.
- **Rtd** – Refer to page 160 for information on setting up additional parameters for this channel I/O type.
- **StrainGage** – Refer to page 162 for information on setting up additional parameters for this channel I/O type.
- **Accelerometer** – Refer to page 167 for information on setting up additional parameters for this channel I/O type.
• Bridge – Refer to page 168 for information on setting up additional parameters for this channel I/O type.

• Thermistor – Refer to page 172 for information on setting up additional parameters for this channel I/O type.

• Resistance – Refer to page 173 for information on setting up additional parameters for this channel I/O type.

• MultiSensor – A MultiSensor I/O type means that the channel supports multiple sensors types. You must specify the sensor type that is connected to the channel using the SupportedChannelInfo.MultiSensorType property, as described in the following subsections.

**Setting Up Voltage Input Channels**

To determine whether a specific channel supports voltage inputs or multiple sensor types, use the SupportedChannelInfo.IOType property. If the value of IOType is MultiSensor, you must set the multisensor type to VoltageIn using the SupportedChannelInfo.MultiSensorType property to use the channel for voltage measurements.

**Note:** You can read a single voltage value from one channel using the AnalogInputSubsystem.GetSingleValueAsVolts method. If the analog input subsystem supports simultaneous operations (AnalogInputSubsystem.SupportsSimultaneousSampleHold is True), you can read a single voltage value from all channels using the AnalogInputSubsystem.GetSingleValuesAsVolts method. Refer to page 176 for more information.

If you are acquiring data to a buffer, you can read the voltage value from the specified channels using the OlBuffer.GetDataAsVolts method. Refer to page 223 for more information.

**Termination Resistor**

Some voltage input channels support a bias return termination resistor. To determine if the channel supports input termination, use the SupportedChannelInfo.SupportsInputTermination property.

The bias return termination resistor is typically enabled for floating and grounded voltage sources. It is typically disabled for voltage sources with grounded references. Refer to the documentation for your device for wiring information.

You can enable or disable the bias return termination resistor using the SupportedChannelInfo.InputTerminationEnabled property. If this property is True, the termination resistor is enabled. If this property is False, the termination resistor is not used.
Sensor Gain and Offset

If you want to read a value from a channel in engineering units, like pressure, and your channel supports voltage measurements only, you can specify the gain and offset for the sensor using the `SupportedChannelInfo.SensorGain` and `SupportedChannelInfo.SensorOffset` properties.

**Note:** If the channel supports an I/O type other than voltage, such as thermocouple, RTD, thermistor, resistance, current, strain gage, or bridge, use the properties specific to these I/O types instead of the sensor gain and offset. For example, if you want to read a temperature value from a thermocouple input, use the `ThermocoupleType` property, described on page 158, instead of the sensor gain and offset.

The sensor gain and offset are used to scale a sample from raw counts to a sensor format. The scaling occurs in two steps. First, the raw count value is converted to prescaled voltage using the gain applied to the input signal. Then, the prescaled voltage is scaled using the following equation:

\[ y = mx + b \]

where \( y \) is the scaled sensor value, \( m \) is the sensor gain, \( x \) is the prescaled value in voltage, and \( b \) is the sensor offset.

The following example shows how to set the sensor gain and offset of channel 0 of the analog input subsystem using the `SupportedChannels` object:

**Visual C#**

```
SupportedChannelInfo Ch0Info =
    ainSS.SupportedChannels.GetChannelInfo(
        SubsystemType.AnalogInput, 0);

// Set the sensor gain and offset
Ch0Info.SensorGain = 2;
Ch0Info.SensorOffset = 10;
```

**Visual Basic**

```
Dim Ch0Info As SupportedChannelInfo =
    ainSS.SupportedChannels.GetChannelInfo(
        SubsystemType.AnalogInput, 0)

' Set the sensor gain and offset
Ch0Info.SensorGain = 2
Ch0Info.SensorOffset = 10
```
**Setting Up Current Input Channels**

To determine if the analog input subsystem supports current inputs, use the `AnalogInputSubsystem.SupportsCurrent` property.

If this value is True, determine whether the specific channel supports current or multiple sensor types using the `SupportedChannelInfo.IOType` property. If the value of `IOType` is `MultiSensor`, you must set the multisensor type to `Current` using the `SupportedChannelInfo.MultiSensorType` property to use the channel for current measurements.

Some current channels support a bias return termination resistor. To determine if the channel supports input termination, use the `SupportedChannelInfo.SupportsInputTermination` property.

The bias return termination resistor is typically enabled for floating and grounded current sources. It is typically disabled for current sources with grounded references. Refer to the documentation for your device for wiring information.

You can enable or disable the bias return termination resistor using the `SupportedChannelInfo.InputTerminationEnabled` property. If this property is True, the termination resistor is enabled. If this property is False, the termination resistor is not used.

---

**Note:** You can read a single current value from one channel using the `AnalogInputSubsystem.GetSingleValueAsCurrent` method. Refer to page 176 for more information.

If you are acquiring data to a buffer, you can read the current value from the specified channels using the `OlBuffer.GetDataAsCurrent` method. Refer to page 222 for more information.

---

**Setting Up Thermocouple Input Channels**

To determine if the analog input subsystem supports thermocouple inputs, use the `AnalogInputSubsystem.SupportsThermocouple` property.

If this value is True, determine whether the specific channel supports thermocouple inputs or multiple sensor types using the `SupportedChannelInfo.IOType` property. If the value of `IOType` is `MultiSensor`, you must set the multisensor type to `Thermocouple` using the `SupportedChannelInfo.MultiSensorType` property to use the channel for thermocouple measurements.

For channels that support thermocouples, you can set the following properties:

- Thermocouple input type, described on this page
- CJC source, described on page 159
Note: You can read a single temperature value from one channel using the `AnalogInputSubsystem.GetSingleValueAsTemperature` method. If the analog input subsystem supports simultaneous operations (`AnalogInputSubsystem.SupportsSimultaneousSampleHold` is True), you can read a single temperature value from all channels using the `AnalogInputSubsystem.GetSingleValuesAsTemperature` method. Refer to page 176 for more information.

If you are acquiring data to a buffer, you can read the temperature from the specified channels using the `OlBuffer.GetDataAsTemperatureByte` or `OlBuffer.GetDataAsTemperatureDouble` method, depending on whether your device returns temperature values as integer or floating-point (4 byte) values. To determine if your subsystem returns floating-point values, use the `AnalogInputSubsystem.ReturnsFloats` property. Refer to page 223 for more information.

**Thermocouple Input Types**

If the subsystem supports thermocouple inputs, specify the type of thermocouple that is connected to the input channel using the `SupportedChannelInfo.ThermocoupleType` property. The following thermocouple types are defined:

- None – Specifies voltage rather than temperature
- J – Specifies a J thermocouple type
- K – Specifies a K thermocouple type
- B – Specifies a B thermocouple type
- E – Specifies a E thermocouple type
- N – Specifies a N thermocouple type
- R – Specifies a R thermocouple type
- S – Specifies a S thermocouple type
- T – Specifies a T thermocouple type

If the thermocouple type is set to None, data is returned in voltage rather than temperature. If the thermocouple type is set for any of the other defined thermocouple types, the data is returned in temperature; you can specify the units as degrees C, F, or K.

Note: If the `AnalogInputSubsystem.SupportsTemperatureDataInStream` is True, each channel’s `ThermocoupleType` property is set to the value that was stored on the device when the subsystem was last configured. If `AnalogInputSubsystem.SupportsTemperatureDataInStream` is False, the default thermocouple type is J.

You can get the temperature range for a specified thermocouple type using the `Utility.GetThermocoupleRange` method.
CJC Sources

Some devices do temperature conversion hardware based on the value of an internal CJC (cold junction compensation) channel. Every sample in the data stream corresponds to a single (typically, floating-point) value that represents either the temperature (in degrees C) or the voltage of the input channel, based on its thermocouple type.

Other devices return A/D input values as raw counts and the DT-Open Layers for .NET Class Library converts these values into temperatures or voltage based on the thermocouple input type and the value of the CJC channel.

To determine if your subsystem does temperature conversion in hardware, use the `AnalogInputSubsystem. SupportsTemperatureDataInStream` property. If this property returns True, temperature conversion is done by the DT-Open Layers for .NET Class Library.

To determine if the analog input subsystem supports a CJC (cold junction compensation) source that is internal to the hardware, use the `AnalogInputSubsystem. SupportsCjcSourceInternal` property. To determine if the analog input subsystem supports channels that are used for CJC, use the `AnalogInputSubsystem. SupportsCjcSourceChannel` property.

If the analog input subsystem supports one or more channels that are used for CJC, you can determine which CJC channel is associated with a specific input channel using the `SupportedChannelInfo.CjcChannel` property. This property applies only to devices that support a channel (not an internal source) as the CJC source. By default, channel 0 is used as the CJC source.

Note: Some devices that support temperature conversion in hardware also provide the option of returning CJC values in the data stream. This option is seldom used, but is provided if you want to implement your own temperature conversion algorithms in software when using continuous operations.

To determine if the subsystem supports interleaving CJC temperature values with A/D values (either voltage or temperature depending on the thermocouple type) in the data stream, use the `AnalogInputSubsystem.SupportsInterleavedCjcTemperaturesInStream` property.

By default, the subsystem is disabled from returning CJC values in the data stream. To enable the subsystem to return CJC values in the data stream, use the `AnalogInputSubsystem. ReturnCjcTemperaturesInStream` property. When enabled, two (typically floating-point) values are returned in the data stream for each channel: the first value represents the temperature or voltage of the input channel (based on the thermocouple type of the input), and the second value represents the CJC temperature, in degrees C. Generally, in this configuration, a thermocouple type of None is specified for each channel; use `GetDataAsVolts`, described on page 222 to read the data). If you return CJC values in the data stream, ensure that you allocate a buffer that is twice as large to accommodate the CJC values (number of samples x 2).

Refer to page 176 and page 223 for more information on reading CJC values.
Setting Up RTD Input Channels

To determine if the analog input subsystem supports RTD inputs, use the AnalogInputSubsystem.SupportsRTD property.

If this value is True, determine whether the specific channel supports RTDs or multiple sensor types using the SupportedChannelInfo.IOType property. If the value of IOType is MultiSensor, you must set the multisensor type to Rtd using the SupportedChannelInfo.MultiSensorType property to use the channel for RTD measurements.

In an RTD measurement, the measurement device reads the voltage drop across the RTD as the resistance changes and converts the voltage to the appropriate temperature using the Callendar-Van Dusen transfer function:

\[ R_T = R_0 \left[ 1 + A T + B T^2 + C T^3 (T - 100) \right] \]

where,

- \( R_T \) is the resistance at temperature.
- \( R_0 \) is the resistance at 0° C.
- \( A, B, \) and \( C \) are the Callendar-Van Dusen coefficients for a particular RTD type. (The value of \( C \) is 0 for temperatures above 0° C.)

For channels that support RTD inputs, you must specify the type of RTD that is connected to the input channel using the SupportedChannelInfo.RTDTType property. To specify the R0 coefficient, use the SupportedChannelInfo.RtdR0 property. To specify the A coefficient, use the SupportedChannelInfo.RtdACoefficient property. To specify the B coefficient, use the SupportedChannelInfo.RtdBCoefficient property. To specify the C coefficient, use the SupportedChannelInfo.RtdCCoefficient property.

Table 66 lists the values that are supported for these properties:
If you specify a value of Pt3850 for `SupportedChannelInfo.RTDType`, you must also specify `SupportedChannelInfo.RtdR0`, unless you are using a 100 Ω RTD (the default value).

If you specify a value of Custom for `SupportedChannelInfo.RTDType`, you must specify the values for `SupportedChannelInfo.RtdR0`, `SupportedChannelInfo.RtdACoefficient`, `SupportedChannelInfo.RtdBCoefficient`, and `SupportedChannelInfo.RtdCCoefficient`. Otherwise, the software automatically sets the appropriate value for `SupportedChannelInfo.RtdR0`, `SupportedChannelInfo.RtdACoefficient`, `SupportedChannelInfo.RtdBCoefficient`, and `SupportedChannelInfo.RtdCCoefficient` based on the selected RTD type.

**Note:** If the `AnalogInputSubsystem.SupportsTemperatureDataInStream` property is True, each channel’s `RTDType` property is set to the value that was stored on the device when the subsystem was last configured.

Use the `SupportedChannelInfo.SensorWiringConfiguration` property to specify the wiring configuration (two-wire, three-wire, or four-wire) for the RTD.

RTD data on most devices is represented as floating-point values (4 bytes). To determine if your subsystem returns floating-point values, use the `AnalogInputSubsystem.ReturnsFloats` property.
**Note:** You can read a single temperature value from one channel using the `AnalogInputSubsystem.GetSingleValueAsTemperature` method. If the analog input subsystem supports simultaneous operations (`AnalogInputSubsystem.SupportsSimultaneousSampleHold` is True), you can read a single temperature value from all channels using the `AnalogInputSubsystem.GetSingleValuesAsTemperature` method. Refer to page 176 for more information.

If you are acquiring data to a buffer, you can read the temperature from the specified channels using the `OIBuffer.GetDataAsTemperatureByte` or `OIBuffer.GetDataAsTemperatureDouble` method. Refer to page 223 for more information.

---

**Setting Up Strain Gage Input Channels**

To determine if the analog input subsystem supports strain gage measurements, use the `AnalogInputSubsystem.SuchpportStrainGage` property.

If this value is True, determine whether the specific channel supports strain gage measurements or multiple sensor types using the `SupportedChannelInfo.IOType` property. If the value of `IOType` is MultiSensor, you must set the multisensor type to StrainGage using the `SupportedChannelInfo.MultiSensorType` property to use the channel for strain gage measurements.

For channels that support strain gages, you can set the following properties for the channel:

- TEDS information, if supported, as described on page 163
- Strain Gage configuration, described on page 165
- Poisson ratio, described on page 166
- Lead wire resistance, described on page 166
- Gage factor, described on page 166
- Nominal resistance, described on page 166
- Offset nulling value, described on page 166
- Shunt calibration resistor and value, described on page 167
Using the OpenLayers.Base Namespace

Note: You must set the excitation source and value for the subsystem, as described on page 203.

You can read a single microstrain value from a strain gage channel using the
AnalogInputSubsystem.GetSingleValueAsStrain method. For a device that supports simultaneous A/Ds, you can acquire a single value from each analog input channel and return the data as an array of values in microstrain using the
AnalogInputSubsystem.GetSingleValuesAsStrain method. Refer to page 176 for more information.

If you are acquiring data to a buffer, you can read data from each strain gage, in microstrain, using the OlBuffer.GetDataAsStrain method. Refer to page 224 for more information.

In some cases, you may wish to use a rosette, which is arrangement of two or more closely positioned strain gage grids that are oriented to measure the normal strains along different directions in the underlying surface of a test material. The DT-Open Layers for .NET Class Library supports rectangular and delta rosettes; tee rosettes are not supported.

A rectangular rosette is an arrangement of three strain gage grids where the second grid is angularly displaced from the first grid by 45 degrees and the third grid is angularly displaced from the first grid by 90 degrees. In this arrangement, each strain gage grid (configured as a quarter bridge strain gage) corresponds to an analog input channel. You can read the strain value from each analog input channel individually, and if desired, use the utility method Utility.ComputeRectangularRosette to calculate the minimum and maximum principal strain values and their associated angles (in degrees).

A delta rosette is an arrangement of three strain gage grids where the second grid is angularly displaced from the first grid by 60 degrees and the third grid is angularly displaced from the first grid by 120 degrees. In this arrangement, each strain gage grid (configured as a quarter bridge strain gage) corresponds to an analog input channel. You can read the strain value from each analog input channel individually, and if desired, use the utility method Utility.ComputeDeltaRosette to calculate the minimum and maximum principal strain values and their associated angles (in degrees).

TEDS for Strain Gages

If your strain gage supports a TEDS interface, you can read the TEDS data from the strain gage directly using the SupportedChannelInfo.StrainGageTeds.ReadHardwareTeds method, or from a TEDS data file using the SupportedChannelInfo.StrainGageTeds.ReadVirtualTeds method.

Note: The properties in the StrainGageTeds class are read-only. It is up the application to read the value of these properties and to apply the appropriate values to the SupportedChannelInfo strain gage properties.

Table 67 lists the properties that you can read to access the TEDS data for a strain gage.

Strain Gage Configuration

For an analog input channel that supports a strain gage input, you can specify one of the following configurations using the `SupportedChannelInfo.StrainGageBridgeConfiguration` property:

- **FullBridgeBending** – This configuration uses four active gages to measure bending strain. This configuration rejects axial strain, compensates for temperature, and compensates for lead resistance.

- **FullBridgeBendingPoisson** – This configuration uses four active gages to measure bending strain. This configuration also rejects axial strain, compensates for temperature, compensates for lead resistance, and compensates for the aggregate effect on the principle strain measurement due to the Poisson ratio of the specimen material.

- **FullBridgeAxialPoisson** – This configuration uses four active gages to measure axial strain. This configuration also compensates for temperature, rejects bending strain, compensates for lead resistance, and compensates for the aggregate effect on the principle strain measurement due to the Poisson ratio of the specimen material.

- **HalfBridgePoisson** – This configuration uses two active gages to measure either axial or bending strain. This configuration compensates for temperature, and compensates for the aggregate effect on the principle strain measurement due to the Poisson ratio of the specimen material.

- **HalfBridgeBending** – This configuration uses two active gages to measure bending strain. This configuration rejects axial strain and compensates for temperature.

</table>
- **QuarterBridge** – This configuration uses a single active gage to measure axial or bending strain. You must supply an external resistor that matches the nominal resistance of the bridge to complete the bridge externally.

  __Note:__ If you are using a rectangular or delta rosette, configure each channel to use the QuarterBridge configuration.

- **QuarterBridgeTempComp** – This configuration uses one active gage and one dummy gage to measure axial and bending strain while compensating for temperature.

**Strain Gage Poisson Ratio**

For an analog input channel that uses the FullBridgeBendingPoisson, FullBridgeAxialPoisson, and HalfBridgePoisson bridge configuration, you can specify the Poisson ratio of the specimen material using the `SupportedChannelInfo.StrainGagePoissonRatio` property. The Poisson ratio is a material-dependent constant that is the ratio of transverse (perpendicular) contraction to axial strain.

**Strain Gage Lead Wire Resistance**

For an analog input channel that supports a strain gage input and does not use remote sensing, you can specify the lead wire resistance of the bridge, in ohms, using the `SupportedChannelInfo.StrainGageLeadWireResistance` property.

If remote sensing is used, specify 0 for this property.

**Gage Factor**

For an analog input channel that supports a strain gage input, you can specify the gage factor of the strain gage using the `SupportedChannelInfo.StrainGageGageFactor` property.

**Strain Gage Nominal Resistance**

For an analog input channel that supports a strain gage input, you can specify the nominal resistance of the bridge (R_g), in ohms, when it is not under strain or load using the `SupportedChannelInfo.StrainGageNominalResistance` property.

**Strain Gage Offset Nulling**

For an analog input channel that supports a strain gage input, a balanced bridge produces zero volts under ideal conditions with zero strain applied. In practice, however, the output of a bridge in an unstrained condition is offset from zero slightly due to imperfect matching of bridge resistances.

You can adjust the offset of the channel by performing offset nulling on the channel. To perform offset nulling, read the value of the bridge in an unstrained condition using the `AnalogInputSubsystem.GetSingleValueAsVolts` method. Then, specify the value that you read using the `SupportedChannelInfo.StrainGageOffsetNullingValueInVolts` property. Internally, this value is subtracted from all subsequent measurements before the voltage is converted to strain.
**Strain Gage Shunt Calibration**

To determine if the analog input subsystem supports shunt calibration, use the `AnalogInputSubsystem. SupportsShuntCalibration` property.

You can use shunt calibration to correct span errors in the measurement path. You can also use shunt calibration to verify the integrity of the setup by turning on the shunt resistor before you acquire data.

If you want to use the internal shunt calibration resistor provided by the device, ensure that the internal RSHUNT+ and RSHUNT– lines are connected across the gage and that no strain is applied to the specimen, and then enable the resistor by setting the `SupportedChannelInfo.StrainGageShuntCalibrationResistorEnabled` property to True. (Be sure to set this value back to False when the shunt calibration procedure is complete.)

Once the internal shunt resistor is enabled or you have connected your own shunt resistor to the bridge, read the value of the bridge using the `AnalogInputSubsystem.GetSingleValueAsStrain` method. Then, divide the expected value of the bridge by the actual value that you read, and specify the result, in microstrain, using the `SupportedChannelInfo.StrainGageShuntCalibrationValue` property. Internally, the software multiplies the channel measurement with this value to adjust the gain of the device.

Refer to the user’s manual for your device for more information on shunt calibration.

**Setting Up Accelerometer (IEPE) Input Channels**

To determine if the analog input subsystem supports IEPE inputs, use the `AnalogInputSubsystem.SupportsIepe` property.

Determine whether the specific channel supports IEPE inputs or multiple sensor types using the `SupportedChannelInfo.IOType` property. If the value of `IOType` is MultiSensor, you must set the multisensor type to Accelerometer using the `SupportedChannelInfo.MultiSensorType` property to use the channel for accelerometer measurements.

For channels that support accelerometers (IEPE inputs), you can set the following properties:

- Coupling
- Excitation current source

**Coupling**

To determine if the analog input subsystem supports DC coupling (where DC offset is included), use the `AnalogInputSubsystem. SupportsDCCoupling` property. To determine if the analog input subsystem supports AC coupling (where the DC offset is removed), use the `AnalogInputSubsystem.SupportsACCoupling` property.

You can specify one of the coupling type using the `SupportedChannelInfo.Coupling` property. By default, DC coupling is used.
Excitation Current Source Values

To determine if the analog input subsystem supports an internal excitation current source, use the \texttt{AnalogInputSubsystem.SupportsInternalExcitationCurrentSrc} property. To determine if the analog input subsystem supports an external excitation current source, use the \texttt{AnalogInputSubsystem.SupportsExternalExcitationCurrentSrc} property.

You can specify the excitation current source (Internal, External, or Disabled) using the \texttt{SupportedChannelInfo.ExcitationCurrentSource} property. By default, the excitation current source is disabled.

If you set the excitation current source to Internal, you can also set the value of the excitation current source using the \texttt{SupportedChannelInfo.ExcitationCurrentValue} property. To determine what current source values are supported by the subsystem, use the \texttt{AnalogInputSubsystem.SupportedExcitationCurrentValues} property. By default, the first value in the list of supported values is used.

Setting Up Bridge-Based Sensors

To determine if the analog input subsystem supports bridge-based sensors or general-purpose bridges, use the \texttt{AnalogInputSubsystem.SupportsBridge} property.

If this value is True, determine whether the specific channel supports bridge measurements or multiple sensor types using the \texttt{SupportedChannelInfo.IOType} property. If the value of \texttt{IOType} is MultiSensor, you must set the multisensor type to Bridge using the \texttt{SupportedChannelInfo.MultiSensorType} property.

For full-bridge-based sensors, you can set the following properties for the channel:

- TEDS information, if available, as described on page 169
- Bridge configuration, described on page 171
- Transducer capacity, described on page 171
- Transducer rated output, described on page 171
- Nominal resistance, described on page 171
- Lead wire resistance, described on page 171
- Offset nulling value, described on page 171
- Shunt calibration resistor and value, described on page 172
Note: You must set the excitation source and value for the subsystem, as described on page 203.

For full-bridge-based sensors, you can read a single value in the native engineering units of the sensor using the `AnalogInputSubsystem.GetSingleValueAsBridgeBasedSensor` method. For a device that supports simultaneous A/Ds, you can acquire a single value from each bridge-based sensor and return the data as an array of values (in the native engineering units of the sensor) using the `AnalogInputSubsystem.GetSingleValuesAsBridgeBasedSensor` method. Refer to page 176 for more information.

If you are acquiring data to a buffer, you can read data from each bridge-based sensor (in the native engineering units of the sensor) using the `OlBuffer.GetDataAsBridgeBasedSensor` method. Refer to page 224 for more information.

For general-purpose bridges, you can read a single normalized bridge output value, in volts, from the bridge using the `AnalogInputSubsystem.GetSingleValueAsNominalBridgeOutput` method. If you are acquiring data to a buffer, you can read the normalized bridge output value from the specified channels, in mV/Vexe, using the `OlBuffer.GetDataAsNormalizedBridgeOutput` method. Refer to page 176 and page 224 for more information.

**TEDS for Bridge-Based Sensors**

If your bridge-based sensor or transducer supports a TEDS interface, you can read the TEDS data from the sensor directly using the `SupportedChannelInfo.BridgeSensorTeds.ReadHardwareTeds` method, or from a TEDS data file using the `SupportedChannelInfo.BridgeSensorTeds.ReadVirtualTeds` method.

Note: The properties in the BridgeSensorTeds class are read-only. It is up the application to read the value of these properties and to apply the appropriate values to the SupportedChannelInfo strain gage properties.

Table 68 lists the properties that you can read to access the TEDS data for a bridge-based sensor.

**Bridge Configuration**

For an analog input channel that supports a bridge input, you can specify one of the following configurations using the `SupportedChannelInfo.BridgeConfiguration` property:

- **FullBridge** – Use this configuration for bridge-based sensors or transducers, such as load cells, or general-purpose bridges that use four active gages.
- **HalfBridge** – Use this configuration for general-purpose bridges that use two active gages.
- **QuarterBridge** – Use this configuration for general-purpose bridges that use one active gages.

**Transducer Capacity**

Use the `SupportedChannelInfo.TransducerCapacity` property to specify or return the full-scale range of the bridge-based sensor or transducer in its native engineering units. This value is supplied by the manufacturer of the bridge-based sensor or transducer.

**Transducer Rated Output**

Use the `SupportedChannelInfo.TransducerRatedOutputInMv` property to specify or return the rated output of the transducer in terms of mV/V excitation. This value is supplied by the manufacturer of the bridge-based sensor or transducer.

**Nominal Resistance**

For an analog input channel that supports a full-bridge-based transducer that does not use remote sensing, you can specify the nominal resistance of the bridge (\(R_g\)), in ohms, when it is not under strain or load using the `SupportedChannelInfo.StrainGageNominalResistance` property.

**Lead Wire Resistance**

For an analog input channel that supports a full-bridge-based transducer that does not use remote sensing, you can specify the lead wire resistance of the bridge, in ohms, using the `SupportedChannelInfo.StrainGageLeadWireResistance` property.

If remote sensing is used, specify 0 for this property.

**Offset Nulling**

For an analog input channel that supports a strain gage input, a balanced bridge produces zero volts under ideal conditions with zero strain applied. In practice, however, the output of a bridge in an unstrained condition is offset from zero slightly due to imperfect matching of bridge resistances.

You can adjust the offset of the channel by performing offset nulling on the channel. To perform offset nulling, read the value of the bridge in an unstrained condition using the `AnalogInputSubsystem.GetSingleValueAsVolts` method. Then, specify the value that you read using the `SupportedChannelInfo.StrainGageOffsetNullingValueInVolts` property.
Internally, this value is subtracted from all subsequent measurements before the voltage is converted to strain.

**Shunt Calibration**

To determine if the analog input subsystem supports shunt calibration, use the `AnalogInputSubsystem.SupportsShuntCalibration` property.

You can use shunt calibration to correct span errors in the measurement path. You can also use shunt calibration to verify the integrity of the setup by turning on the shunt resistor before you acquire data.

If you want to use the internal shunt calibration resistor provided by the device, ensure that the internal RSHUNT+ and RSHUNT– lines are connected across the gage and that no strain is applied to the specimen, and then enable the resistor by setting the `SupportedChannelInfo.StrainGageShuntCalibrationResistorEnabled` property to True. (Be sure to set this value back to False when the shunt calibration procedure is complete.)

Once the internal shunt resistor is enabled or you have connected your own shunt resistor to the bridge, read the value of the bridge using the `AnalogInputSubsystem.GetSingleValueAsStrain` method. Then, divide the expected value of the bridge by the actual value that you read, and specify the result, in microstrain, using the `SupportedChannelInfo.StrainGageShuntCalibrationValue` property. Internally, the software multiplies the channel measurement with this value to adjust the gain of the device. Refer to the user’s manual for your device for more information on shunt calibration.

**Setting up Thermistor Input Channels**

To determine if the analog input subsystem supports thermistor inputs, use the `AnalogInputSubsystem.SupportsThermistor` property.

If this value is True, determine whether the specific channel supports thermistors or multiple sensor types using the `SupportedChannelInfo.IOType` property. If the value of `IOType` is `MultiSensor`, you must set the multisensor type to Thermistor using the `SupportedChannelInfo.MultiSensorType` property to use the channel for thermistor measurements.

The resistance of NTC thermistors increases with decreasing temperature. The resistance to temperature relationship is characterized by the Steinhart-Hart equation:

\[
\frac{1}{T} = A + B \ln R + C \ln(R)^3
\]

where,

- T is the temperature, in degrees Kelvin.
- R is the resistance at T, in Ohms.
- A, B, and C are the Steinhart-Hart coefficients for a particular thermistor type and value, and are supplied by the thermistor manufacturer.
The value of the A, B, and C coefficients depend on the thermistor type and value that you are using. Specify the A coefficient using the `SupportedChannelInfo.ThermistorACoefficient` property. Specify the B coefficient using the `SupportedChannelInfo.ThermistorBCoefficient` property. Specify the C coefficient using the `SupportedChannelInfo.ThermistorCCoefficient` property.

Use the `SupportedChannelInfo.SensorWiringConfiguration` property to specify the wiring configuration (two-wire, three-wire, or four-wire) for the thermistor.

---

**Note:** You can read a single temperature value from one channel using the `AnalogInputSubsystem.GetSingleValueAsTemperature` method. Refer to page 176 for more information.

If you are acquiring data to a buffer, you can read the temperature from the specified channels using the `OlBuffer.GetDataAsTemperatureByte` or `OlBuffer.GetDataAsTemperatureDouble` method. Refer to page 223 for more information.

---

### Setting Up Resistance Measurement Channels

To determine if the analog input subsystem supports resistance measurements, use the `AnalogInputSubsystem.SupportsResistance` property.

If this value is True, determine whether the specific channel supports resistance or multiple sensor types using the `SupportedChannelInfo.IOType` property. If the value of `IOType` is `MultiSensor`, you must set the multisensor type to Resistance using the `SupportedChannelInfo.MultiSensorType` property to use the channel for resistance measurements.

To determine if the analog input subsystem supports an internal excitation current source, use the `AnalogInputSubsystem.SupportsInternalExcitationCurrentSrc` property. To determine if the analog input subsystem supports an external excitation current source, use the `AnalogInputSubsystem.SupportsExternalExcitationCurrentSrc` property.

If the analog input channel supports a programmable current source, you can specify one of the excitation current source (Internal, External, or Disabled (the default value)) using the `SupportedChannelInfo.ExcitationCurrentSource` property.

If you set the excitation current source to Internal, you can also set the value of the excitation current source using the `SupportedChannelInfo.ExcitationCurrentValue` property. To determine what current source values are supported by the subsystem, use the `AnalogInputSubsystem.SupportedExcitationCurrentValues` property. By default, the first value in the list of supported values is used.
Note: You can read a single resistance value from one channel using the `AnalogInputSubsystem.GetSingleValueAsResistance` method. Refer to page 176 for more information.

If you are acquiring data to a buffer, you can read resistance values from the specified channels using the `OlBuffer.GetDataAsResistance` method. Refer to page 223 for more information.

Use the `SupportedChannelInfo.SensorWiringConfiguration` property to specify the wiring configuration (two-wire, three-wire, or four-wire) for the resistance measurement.
Setting Up and Configuring a Subsystem

Once you have gotten a subsystem and know about its supported channels, you can set up the subsystem for the I/O operation that you want to perform, and then configure it.

The way you set up the subsystem depends on the operation that you want to perform. Refer to the following sections for specific information on setting up I/O operations:

- For analog I/O operations, refer to page 176.
- For digital I/O operations, refer to page 229.
- For counter/timer operations, refer to page 232.
- For tachometer operations, refer to page 251.
- For quadrature decoder operations, refer to page 253.
- For simultaneous operations, refer to page 255.

Call the Config method within the appropriate subsystem class to configure the subsystem before performing the I/O operation.
Performing Analog I/O Operations

Using the DT-Open Layers for .NET Class Library, you can perform the following types of analog I/O operations.

- Single value analog input, described below
- Single value analog output, described on page 180
- Continuous pre- and post-trigger analog input using a start and reference trigger, described on page 185
- Continuous post-trigger analog input, described on page 187
- Continuous pre-trigger analog input, described on page 190
- Continuous about-trigger analog input, described on page 193
- Continuously paced analog output, described on page 196
- Continuous waveform generation analog output, described on page 198

Note: On some devices, an AnalogOutputSubsystem element is used to set an analog threshold trigger; these elements support single-value analog output operations only.

Single-Value Analog Input Operations

Single-value operations are the simplest to use but offer the least flexibility and efficiency. In a single-value analog input operation, a single data value is read from a single channel. The operation occurs immediately.

To determine if the subsystem supports single-value operations, use the AnalogInputSubsystem.SupportsSingleValue property. If this property returns a value of True, the subsystem supports single-value operations.

Once you have an AnalogInputSubsystem object, as described on page 146, and set up the channels as described on page 154, set up the AnalogInputSubsystem object for a single value operation as follows:

2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the AnalogInputSubsystem.ChannelType property. See page 201 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the AnalogInputSubsystem.Encoding property. See page 202 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the AnalogInputSubsystem.VoltageRange property. See page 202 for more information on voltage ranges.
5. (Optional) For measurements that require an excitation source (such as resistance, accelerometers, strain gages, or bridges), set the excitation voltage source for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property, and if using an internal excitation source, set the value of the internal excitation voltage source using the `AnalogInputSubsystem.ExcitationVoltageValue` property. See page 203 for more information on excitation voltage sources.

6. (Optional) For subsystems that allow you to synchronize operations on multiple devices using a synchronization connector, set the synchronization mode of the analog input subsystem on each device using the `AnalogInputSubsystem.SynchronizationMode` property. See page 203 for more information on synchronization.

7. (Optional) For subsystems that support programmable filter, set the filter type using the `AnalogInputSubsystem.DataFilterType` property. See page 204 for more information.

8. Configure the subsystem using the `AnalogInputSubsystem.Config` method.

9. Acquire a single value using one of the following methods:

   **For Devices with Multiplexed A/D architectures:**
   
   - `AnalogInputSubsystem.GetSingleValueAsRaw` – Acquires a single value from a specified analog input channel using a specified gain, and returns the value as a raw count.
   
   - `AnalogInputSubsystem.GetSingleValueAsVolts` – Acquires a single value from a specified analog input channel using a specified gain, and returns the data as a voltage.

   For subsystems that support temperature conversions in hardware (`SupportsTemperatureDataInStream` is True), a voltage value is returned only if the specified channel is configured for a `ThermocoupleType` of None. If the channel is configured for any other `ThermocoupleType`, an exception is raised. Refer to page 158 for more information on thermocouples.

   - `AnalogInputSubsystem.GetSingleValueAsSensor` – Acquires a single value from a specified analog input channel at a specified gain, and returns the data as a sensor value.
   
   - `AnalogInputSubsystem.GetSingleValueAsCurrent` – For analog input subsystems that support current measurements, acquires a single current value from a specified analog input channel, and returns the data, in Amperes, as a floating-point value.
   
   - `AnalogInputSubsystem.GetSingleValueAsTemperature` – Overloaded method. Acquires a single temperature value from a specified analog input channel and returns the temperature data in the units you specify.

   For subsystems that support temperature conversions in hardware (`SupportsTemperatureDataInStream` is True), a temperature value is returned only if the specified channel is configured for a `ThermocoupleType` other than None. Otherwise, an exception is raised. Refer to page 158 for more information on thermocouples.
- **AnalogInputSubsystem.GetSingleCjcValueAsTemperature** – For analog input subsystems that support thermocouples, acquires a single CJC temperature value for a specified input channel and returns the temperature in the units you specify.

This function is seldom needed. It is provided in the rare case when you want the application program, instead of the device, to correct and linearize temperature values based on the CJC temperature. To use this method, your device must support thermocouples and the ability to return floating-point values. Refer to page 158 for more information on thermocouples.

- **AnalogInputSubsystem.GetSingleValueAsResistance** – For analog input subsystems that support resistance measurements, acquires a single resistance value from a specified analog input channel, and returns the data, in ohms, as a floating-point value.

- **AnalogInputSubsystem.GetSingleValueAsStrain** – For analog input subsystems that support strain gages, acquires a single value from a specified analog input channel, and returns the data in microstrain.

- **AnalogInputSubsystem.GetSingleValueAsBridgeBasedSensor** – For analog input subsystems that support bridge-based sensors, acquires a single value from a full-bridge-based sensor and returns the data in the native engineering units of the sensor.

- **AnalogInputSubsystem.GetSingleValueAsNormalizedBridgeOutput** – For analog input subsystems that support bridge measurements, acquires a single normalized output value from the bridge and returns the data in volts.

**For Devices with Simultaneous A/D architectures:**

- **AnalogInputSubsystem.GetSingleValuesAsRaw** – Simultaneously acquires a single value from each input channel and returns the values as an array of raw counts.

If your device supports streaming digital inputs, counter/timers, and/or quadrature decoder inputs through the analog input subsystem, **GetSingleValuesAsRaw** returns the data for all the analog input channels, digital input ports, counter/timer channels, and/or quadrature decoder channels.

For meaningful digital input, counter/timer, and/or quadrature decoder data, ensure that you configure and/or start an operation on these subsystems before calling **GetSingleValuesAsRaw**. Refer to page 230 for information on configuring a continuous digital input operation, page 232, page 234, and page 237 for information on configuring counter/timer operations, and page 253 for information on configuring quadrature decoder operations.

- **AnalogInputSubsystem.GetSingleValuesAsVolts** – Simultaneously acquires a single value from each analog input channel and returns the data as an array of voltage values.

For subsystems that support temperature conversions in hardware (SupportsTemperatureDataInStream is True), a voltage value is returned only if the specified channels are configured for a ThermocoupleType of None. If the channel is configured for any other ThermocoupleType, an exception is raised. Refer to page 158 for more information on thermocouples.
- **AnalogInputSubsystem.GetSingleValuesAsSensor** – Simultaneously acquires a single value from each analog input channel and returns the data as an array of sensor values.

- **AnalogInputSubsystem.GetSingleValuesAsTemperature** – For analog input subsystems that support temperature measurements, simultaneously acquires a single temperature value from each analog input channel and returns the data as an array of temperature values, in the units you specify.

  For subsystems that support temperature conversions in hardware (**SupportsTemperatureDataInStream** is True), a temperature value is returned only if the specified channels are configured for a **ThermocoupleType** other than None. Otherwise, an exception is raised. Refer to page 158 for more information on thermocouples.

- **AnalogInputSubsystem.GetSingleCjcValuesAsTemperature** – For analog input subsystems that support thermocouples, simultaneously acquires a single CJC temperature for each input channel and returns the data as an array of temperature values, in the units you specify.

  This function is seldom needed. It is provided in the rare case when you want the application program, instead of the device, to correct and linearize temperature values based on the CJC temperature. To use this method, your device must support simultaneous operations, thermocouples, and the ability to return floating-point values.

- **AnalogInputSubsystem.GetSingleValuesAsStrain** – For analog input subsystems that support strain gages, simultaneously acquires a single value from each analog input channel and returns the data as an array of values in microstrain.

- **AnalogInputSubsystem.GetSingleValuesAsBridgeBasedSensor** – For analog input subsystems that support bridge-based sensors, simultaneously acquires a single value from each full-bridge-based sensor and returns the data as an array of values in the native engineering units of the sensor.

Single-value operations stop automatically when finished; you cannot stop a single-value operation in software.

Refer to the example programs ReadSingleValueAsRaw, ReadSingleValueAsVolts, ReadSingleValueAsSensor, and ReadSingleValueAsTemperature to see how to perform a single-value analog input operation.

---

**Note:** After the acquisition is complete, you can convert a raw count value to voltage using the **AnalogInputSubsystem.RawValueToVolts** method or to a sensor value using the **AnalogInputSubsystem.RawToSensorValues** method. You can also convert a voltage to a temperature value using the **Utility.ConvertVoltsToTemperature** method. If you want to convert voltage to raw counts, you can use the **AnalogInputSubsystem.VoltsToRawValue** method.
Single-Value Analog Output Operations

In a single-value analog output operation, a single data value is output from a single analog output channel. The operation occurs immediately.

To determine if the subsystem supports single-value operations, use the AnalogOutputSubsystem.SupportsSingleValue property. If this property returns a value of True, the subsystem supports single-value operations.

Once you have an AnalogOutputSubsystem object, as described on page 146, set up the AnalogOutputSubsystem object for a single value operation as follows:

2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the AnalogOutputSubsystem.ChannelType property. See page 201 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the AnalogOutputSubsystem.Encoding property. See page 202 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the AnalogOutputSubsystem.VoltageRange property. See page 202 for more information on voltage ranges.
5. Configure the subsystem using the AnalogOutputSubsystem.Config method.
6. Output a single value using one of the following methods:

   **For Devices with Multiplexed D/A architectures:**
   - AnalogOutputSubsystem.SetSingleValueAsRaw – Outputs a single raw count on the specified analog output channel.
   - AnalogOutputSubsystem.SetSingleValueAsVolts – Outputs a single voltage value on a specified analog output channel.

   **For Devices with Simultaneous D/A architectures (SupportsSetSingleValues is True):**
   - AnalogOutputSubsystem.SetSingleValuesAsRaw – Outputs a single raw count on each specified analog output channel. If an analog output channel is not specified, the value of the output channel will not change; the output channel maintains the last value that was written to it.
   - AnalogOutputSubsystem.SetSingleValuesAsVolts – Outputs a single voltage value on each specified analog output channel. If an analog output channel is not specified, the value of the output channel will not change; the output channel maintains the last value that was written to it.

**Note:** You can convert a raw count value to voltage using the AnalogOutputSubsystem.RawValueToVolts method. You can also convert a temperature value to a voltage using the Utility.ConvertTemperatureToVolts method. If you want to convert voltage to raw counts, you can use the AnalogOutputSubsystem.VoltsToRawValue method.
Single-value operations stop automatically when finished; you cannot stop a single-value operation in software.

Refer to the example programs WriteSingleValueAsRaw, WriteSingleValueAsVolts, and WriteSingleValueAsRaw_ProgRanges to see how to perform a single-value analog output operation.
Continuous, Pre- and Post-Trigger Analog Input Operations Using a Start and Reference Trigger

Note: This mode requires use of an `AnalogInputSubsystem.Trigger` object and `AnalogInputSubsystem.ReferenceTrigger` object. Some devices may not support this mode.

Use this mode when you want to acquire pre-trigger data from multiple analog input channels continuously when a specified trigger occurs and, when a reference trigger occurs, acquire a specified number of post-trigger samples.

Once you have an AnalogInputSubsystem object, as described on page 146, and set up the channels as described on page 154, set up the AnalogInputSubsystem object for a continuous operation as follows:

1. Set the `AnalogInputSubsystem.DataFlow` property to Continuous.
2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogInputSubsystem.ChannelType` property. See page 201 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogInputSubsystem.Encoding` property. See page 202 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the `AnalogInputSubsystemVoltageRange` property. See page 202 for more information on voltage ranges.
5. (Optional) For measurements that require an excitation source (such as resistance, accelerometers, strain gages, or bridges), set the excitation voltage source for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property, and if using an internal excitation source, set the value of the internal excitation voltage source using the `AnalogInputSubsystem.ExcitationVoltageValue` property. See page 203 for more information on excitation voltage sources.
6. (Optional) For subsystems that allow you to synchronize operations on multiple devices using a synchronization connector, set the synchronization mode of the analog input subsystem on each device using the `AnalogInputSubsystem.SynchronizationMode` property. See page 203 for more information on synchronization.
7. (Optional) For subsystems that support programmable filter types for measuring temperature, set the filter type using the `AnalogInputSubsystem.DataFilterType` property. See page 204 for more information.
8. Set up the channel list (including setting the gain and inhibit value for each entry), as described on page 204.
Note: If you want to continuously acquire data from the digital input, counter/timer, tachometer, and/or quadrature decoder channels as part of the analog input stream, you must set up the channel list to include these channels. For counter/timer and quadrature decoder channels, you must also configure and start these subsystems before starting the analog input operation. For digital input ports, you must configure the digital input subsystem for a single-value operation before starting the analog input operation. Refer to page 230 for information on continuous digital input operations, page 232, page 234, and page 237 for information on continuous counter/timer operations, page 251 for information on tachometer operations, and page 253 for information on quadrature decoder operations.

9. Set up the clock, as described on page 212.

10. Use the `AnalogInputSubsystem.Trigger.TriggerType` property to specify the trigger type that starts pre-trigger acquisition. Refer to page 213 for more information on supported trigger sources.

11. Use the `AnalogInputSubsystem.ReferenceTrigger.TriggerType` property to specify the trigger type that stops pre-trigger acquisition and starts post-trigger acquisition. Refer to page 213 for more information on supported trigger sources.

12. If the start or reference trigger type is a threshold trigger, do the following:
   a. Specify the channel to use for the threshold trigger using the `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` or `AnalogInputSubsystem.ReferenceTrigger.ThresholdTriggerChannel` property. Refer to page 215 for more information.
   b. Specify a voltage value for the threshold level using the `AnalogInputSubsystem.Trigger.Level` or `AnalogInputSubsystem.ReferenceTrigger.Level` property. Refer to page 215 for more information.

13. Specify the number of samples to acquire after the reference trigger occurs using the `AnalogInputSubsystem.ReferenceTrigger.PostTriggerScanCount` property. Refer to page 217 for more information on the post-trigger scan count.

14. If supported by your device, set up triggered scan mode, as described on page 227.

15. Set up the input buffers, as described on page 218.

16. If your program is running under a heavy CPU load, it is recommended that you set the `AnalogInputSubsystem.SynchronousBufferDone` property to True for synchronous execution of each BufferDoneEvent event in a single worker thread.

17. Configure the subsystem using the `AnalogInputSubsystem.Config` method.

18. Call the `AnalogInputSubsystem.Start` method to start the operation.

Pre-trigger acquisition begins when the start trigger is detected. When the reference trigger occurs, pre-trigger acquisition stops and post-trigger acquisition begins until the number of samples specified by `PostTriggerScanCount` has been acquired. At that point, you will get the last buffer that has valid samples; the remainder of the buffers are cancelled.
Figure 1 illustrates this mode using a channel list of two entries: channel 0 and channel 1. In this example, pre-trigger analog input data is acquired when the start trigger is detected. When the reference trigger occurs, the specified number of post-trigger samples (3, in this example) are acquired.

![Figure 1: Continuous Pre- and Post-Trigger Operations Using a Start and Reference Trigger](image)

If desired, you can also stop a continuous pre- and post-trigger operation using one of the following methods:

- **AnalogInputSubsystem.Stop** – Stops the operation after the current buffer has been filled. The driver raises a BufferDoneEvent event for the completed buffer and sets the OlBuffer.ValidSamples property to the number of samples in the completed buffer. It then raises a BufferDoneEvent event for up to eight inprocess buffers, setting the OlBuffer.ValidSamples property to 0, before raising a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored. Refer to page 218 for more information on buffers, and to page 257 for information on dealing with events.

- **AnalogInputSubsystem.Abort** – Stops the operation immediately without waiting for the current buffer to be filled and sets the OlBuffer.ValidSamples property to the number of samples in the buffer. The driver raises a BufferDoneEvent event for up to eight inprocess buffers, setting the OlBuffer.ValidSamples property to 0, and then raises a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored.

- **AnalogInputSubsystem.Reset** – Stops the operation immediately without waiting for the current buffer to be filled, and reinitializes the subsystem to the default configuration.

**Note:** If you set the AnalogInputSubsystem.AsynchronousStop property to True, control returns to your program after Stop is called. If you set the AsynchronousStop property to False (the default setting) control does not return to your program after Stop is called until the buffer completes or 20 seconds elapses (if the buffer takes longer than 20 seconds to fill). If you try to perform another operation while the stop is in progress, an exception is raised with the error code “SubsystemStopping” and the exception message “The subsystem is in the process of stopping or aborting”.

184
Continuous Post-Trigger Analog Input Operations Using One Channel and One Buffer

Use this mode when you want to acquire one buffer of post-trigger data from one analog input channel.

Once you have an AnalogInputSubsystem object, as described on page 146, and set up the channels as described on page 154, perform the following steps:

1. Set the `AnalogInputSubsystem.DataFlow` property to Continuous.

2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogInputSubsystem.ChannelType` property. See page 201 for more information on channel types.

3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogInputSubsystem.Encoding` property. See page 202 for more information on data encoding.

4. (Optional) Set the voltage range of the subsystem using the `AnalogInputSubsystem.VoltageRange` property. See page 202 for more information on voltage ranges.

5. (Optional) For measurements that require an excitation source (such as resistance, accelerometers, strain gages, or bridges), set the excitation voltage source for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property, and if using an internal excitation source, set the value of the internal excitation voltage source using the `AnalogInputSubsystem.ExcitationVoltageValue` property. See page 203 for more information on excitation voltage sources.

6. (Optional) For subsystems that allow you to synchronize operations on multiple devices using a synchronization connector, set the synchronization mode of the analog input subsystem on each device using the `AnalogInputSubsystem.SynchronizationMode` property. See page 203 for more information on synchronization.

7. (Optional) For subsystems that support programmable filter types for measuring temperature, set the filter type using the `AnalogInputSubsystem.DataFilterType` property. See page 204 for more information.

8. Set up the channel list (including setting the gain and inhibit value for the channel, and adding the channel to the channel list), as described on page 204.

9. Set up the clock, as described on page 212.

10. Use the `AnalogInputSubsystem.Trigger.TriggerType` property to specify the post-trigger source that starts the operation. Refer to page 213 for more information on supported trigger sources.

11. If the trigger type is a threshold trigger, do the following:
   
   a. Specify the channel to use for the threshold trigger using the `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` property. Refer to page 215 for more information.

   b. Specify a voltage value for the threshold level using the `AnalogInputSubsystem.Trigger.Level` property. Refer to page 215 for more information.
12. Call the `AnalogInputSubsystem.GetOneBuffer` method to acquire one buffer of post-trigger data from the specified channel in the channel list. You specify the number of samples to acquire in the call.

This method is synchronous and returns only after the requested data has been acquired or the specified timeout value, in milliseconds, has been exceeded. If the buffer is not filled before the specified timeout value is exceeded, `AnalogInputSubsystem.Abort` is called and a `TimeoutException` is raised. If a `GeneralFailureEvent` or `DriverRuntimeErrorEvent` occurs during acquisition, an `OleDbException` with the appropriate error code is raised.

13. Handle the input buffer, as described on page 221.

When the trigger occurs, post-trigger acquisition begins. When the number of samples have been acquired or the specified timeout value is exceeded, the `OlBuffer` object is returned.

Refer to the example program GetOneBuffer to see how to perform a continuous (post-trigger) analog input operation using one buffer.
Continuous, Post-Trigger Analog Input Operations Using Multiple Buffers

Note: This mode does not support use of the `AnalogInputSubsystem.ReferenceTrigger` object. To use a ReferenceTrigger object, refer to page 185.

Use continuous post-trigger mode when you want to acquire data from multiple analog input channel continuously when a specified start trigger occurs.

To determine if the subsystem supports continuous, post-trigger analog input operations, use the `AnalogInputSubsystem.SupportsContinuous` property. If this property returns a value of True, the subsystem supports continuous post-trigger analog input operations.

Once you have an AnalogInputSubsystem object, as described on page 146, and set up the channels as described on page 154, set up the AnalogInputSubsystem object for a continuous operation as follows:

1. Set the `AnalogInputSubsystem.DataFlow` property to Continuous.
2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogInputSubsystem.ChannelType` property. See page 201 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogInputSubsystem.Encoding` property. See page 202 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the `AnalogInputSubsystem.VoltageRange` property. See page 202 for more information on voltage ranges.
5. (Optional) For measurements that require an excitation source (such as resistance, accelerometers, strain gages, or bridges), set the excitation voltage source for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property, and if using an internal excitation source, set the value of the internal excitation voltage source using the `AnalogInputSubsystem.ExcitationVoltageValue` property. See page 203 for more information on excitation voltage sources.
6. (Optional) For subsystems that allow you to synchronize operations on multiple devices using a synchronization connector, set the synchronization mode of the analog input subsystem on each device using the `AnalogInputSubsystem.SynchronizationMode` property. See page 203 for more information on synchronization.
7. (Optional) For subsystems that support programmable filter types for measuring temperature, set the filter type using the `AnalogInputSubsystem.DataFilterType` property. See page 204 for more information.
8. Set up the channel list (including setting the gain and inhibit value for each entry), as described on page 204.
Note: If you want to continuously acquire data from the digital input, counter/timer, tachometer, and/or quadrature decoder channels as part of the analog input stream, you must set up the channel list to include these channels. For counter/timer and quadrature decoder channels, you must also configure and start these subsystems before starting the analog input operation. For digital input ports, you must configure the digital input subsystem for a single-value operation before starting the analog input operation. Refer to page 230 for information on continuous digital input operations, page 232, page 234, and page 237 for information on continuous counter/timer operations, page 251 for information on tachometer operations, and page 253 for information on quadrature decoder operations.

9. Set up the clock, as described on page 212.

10. Use the AnalogInputSubsystem.Trigger.TriggerType property to specify the post-trigger source that starts the operation. Refer to page 213 for more information on supported trigger sources.

11. If the trigger type is a threshold trigger, do the following:
   a. Specify the channel to use for the threshold trigger using the AnalogInputSubsystem.Trigger.ThresholdTriggerChannel property. Refer to page 215 for more information.
   b. Specify a voltage value for the threshold level using the AnalogInputSubsystem.Trigger.Level property. Refer to page 215 for more information.

12. If supported by your device, set up triggered scan mode, as described on page 227.

13. Set up the input buffers, as described on page 218.

14. If your program is running under a heavy CPU load, it is recommended that you set the AnalogInputSubsystem.SynchronousBufferDone property to True for synchronous execution of each BufferDoneEvent event in a single worker thread.

15. Configure the subsystem using the AnalogInputSubsystem.Config method.

16. Call the AnalogInputSubsystem.Start method to start the continuous post-trigger operation.

When the post-trigger is detected, the device cycles through the channel list, acquiring the value for each ChannelListEntry object in the channel list; this process is defined as a scan. The device then wraps to the start of the channel list and repeats the process continuously until either the allocated buffers are filled or you stop the operation. The event BufferDoneEvent is generated as each buffer is filled with analog input data; refer to page 257 for information on dealing with events and reading the data in the buffer.

Figure 2 illustrates continuous post-trigger mode using a channel list of three entries: channel 0, channel 1, and channel 2. In this example, post-trigger analog input data is acquired on each clock pulse of the A/D sample clock. The device wraps to the beginning of the channel list and repeats continuously.
To stop a continuous post-trigger operation, use one of the following methods:

- **AnalogInputSubsystem.Stop** – Stops the operation after the current buffer has been filled. The driver raises a BufferDoneEvent event for the completed buffer and sets the `OlBuffer.ValidSamples` property to the number of samples in the completed buffer. It then raises a BufferDoneEvent event for up to eight inprocess buffers, setting the `OlBuffer.ValidSamples` property to 0, before raising a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored. Refer to page 218 for more information on buffers, and to page 257 for information on dealing with events.

- **AnalogInputSubsystem.Abort** – Stops the operation immediately without waiting for the current buffer to be filled and sets the `OlBuffer.ValidSamples` property to the number of samples in the buffer. The driver raises a BufferDoneEvent event for up to eight inprocess buffers, setting the `OlBuffer.ValidSamples` property to 0, and then raises a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored.

- **AnalogInputSubsystem.Reset** – Stops the operation immediately without waiting for the current buffer to be filled, and reinitializes the subsystem to the default configuration.

**Notes:** If you set the **AnalogInputSubsystem.AsynchronousStop** property to True, control returns to your program after **Stop** is called. If you set the **AsynchronousStop** property to False (the default setting) control does not return to your program after **Stop** is called until the buffer completes or 20 seconds elapses (if the buffer takes longer than 20 seconds to fill). If you try to perform another operation while the stop is in progress, an exception is raised with the error code “SubsystemStopping,” and the exception message “The subsystem is in the process of stopping or aborting”.

Refer to the example programs ReadBufferedDataAsRaw, ReadBufferedDataAsRawDigTrigger, ReadBufferedDataAsVolts, ReadBufferedDataAsSensor, ReadBufferedDataAsTemperature, and ReadBufferedDataIntoOscilloscope to see how to perform a continuous (post-trigger) analog input operation.
Continuous, Pre-Trigger Analog Input Operations (Legacy Devices)

**Note:** This mode does not support use of the `AnalogInputSubsystem.ReferenceTrigger` object. To use a ReferenceTrigger object, see page 185.

Some older, legacy devices support continuous pre-trigger analog input operations. Use continuous pre-trigger mode when you want to continuously acquire data before a specific external trigger occurs.

To determine if the subsystem supports continuous pre-trigger operations, use the `AnalogInputSubsystem.SupportsContinuousPreTrigger` property. If this property returns a value of True, continuous pre-trigger mode is supported.

Once you have an AnalogInputSubsystem object, as described on page 146, and set up the channels as described on page 154, set up the AnalogInputSubsystem object for a continuous pre-trigger operation as follows:

1. Set the `AnalogInputSubsystem.DataFlow` property to ContinuousPreTrigger.
2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogInputSubsystem.ChannelType` property. See page 201 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogInputSubsystem.Encoding` property. See page 202 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the `AnalogInputSubsystem.VoltageRange` property. See page 202 for more information on voltage ranges.
5. (Optional) For measurements that require an excitation source (such as resistance, accelerometers, strain gages, or bridges), set the excitation voltage source for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property, and if using an internal excitation source, set the value of the internal excitation voltage source using the `AnalogInputSubsystem.ExcitationVoltageValue` property. See page 203 for more information on excitation voltage sources.
6. (Optional) For subsystems that allow you to synchronize operations on multiple devices using a synchronization connector, set the synchronization mode of the analog input subsystem on each device using the `AnalogInputSubsystem.SynchronizationMode` property. See page 203 for more information on synchronization.
7. (Optional) For subsystems that support programmable filter types for measuring temperature, set the filter type using the `AnalogInputSubsystem.DataFilterType` property. See page 204 for more information.
8. Set up the channel list (including setting the gain and the inhibit value for each entry), as described on page 204.
Note: If you want to continuously acquire data from the digital input, counter/timer, tachometer, and/or quadrature decoder channels as part of the analog input stream, you must set up the channel list to include these channels. For counter/timer and quadrature decoder channels, you must also configure and start these subsystems before starting the analog input operation. For digital input ports, you must also configure the digital input subsystem for a single-value operation before starting the analog input operation. Refer to page 230 for information on continuous digital input operations, page 232, page 234, and page 237 for information on continuous counter/timer operations, page 251 for information on tachometer operations, and page 253 for information on quadrature decoder operations.

9. (Optional) Set up the clock, as described on page 212.

10. Use the `AnalogInputSubsystem.Trigger.PretriggerSource` property to specify the trigger source that starts the pre-trigger operation (generally this is a software trigger).

11. Use the `AnalogInputSubsystem.Trigger.TriggerType` property to specify the external post-trigger source that stops the pre-trigger operation. Refer to page 213 for more information on supported trigger sources.

12. If the trigger type is a threshold trigger, do the following:
   a. Specify the channel to use for the threshold trigger using the `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` property. Refer to page 215 for more information.
   b. Specify a voltage value for the threshold level using the `AnalogInputSubsystem.Trigger.Level` property. Refer to page 215 for more information.

13. If supported by your device, set up triggered scan mode, as described on page 227.

14. Set up the input buffers, as described on page 218.

15. Configure the subsystem using the `AnalogInputSubsystem.Config` method.

16. Call the `AnalogInputSubsystem.Start` method to start the continuous pre-trigger operation.

Pre-trigger acquisition begins when the device detects the pre-trigger source and stops when the device detects an external post-trigger source, indicating that the first post-trigger sample was acquired (this sample is ignored). The event `PreTriggerBufferDoneEvent` is generated as each buffer is filled with pre-trigger analog input data; refer to page 257 for information on dealing with events and reading data from the buffers.

Figure 3 illustrates continuous pre-trigger mode using a channel list of three entries: channel 0, channel 1, and channel 2. In this example, pre-trigger analog input data is acquired on each clock pulse of the A/D sample clock. The device wraps to the beginning of the channel list and the acquisition repeats continuously until the post-trigger event occurs. When the post-trigger event occurs, acquisition stops.
To stop a continuous pre-trigger operation, use one of the following methods:

- **AnalogInputSubsystem.Stop** – Stops the operation after the current buffer has been filled. The driver raises a PreTriggerBufferDoneEvent event for the completed buffer and sets the `OlBuffer.ValidSamples` property to the number of samples in the completed buffer. It then raises a PreTriggerBufferDoneEvent event for up to eight inprocess buffers, setting the `OlBuffer.ValidSamples` property to 0, before raising a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored. Refer to page 218 for more information on buffers, and to page 257 for information on dealing with events.

- **AnalogInputSubsystem.Abort** – Stops the operation immediately without waiting for the current buffer to be filled and sets the `OlBuffer.ValidSamples` property to the number of samples in the buffer. The driver raises a PreTriggerBufferDoneEvent event for up to eight inprocess buffers, setting the `OlBuffer.ValidSamples` property to 0, and then raises a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored.

- **AnalogInputSubsystem.Reset** – Stops the operation immediately without waiting for the current buffer to be filled, and reinitializes the subsystem to the default configuration.

**Notes:** If you set the `AnalogInputSubsystem.AsynchronousStop` property to True, control returns to your program after `Stop` is called.

If you set the `AsynchronousStop` property to False (the default setting) control does not return to your program after `Stop` is called until the buffer completes or 20 seconds elapses (if the buffer takes longer than 20 seconds to fill). If you try to perform another operation while the stop is in progress, an exception is raised with the error code "SubsystemStopping" and the exception message "The subsystem is in the process of stopping or aborting".
Continuous, About-Trigger Analog Input Operations (Legacy Devices)

Note: This mode does not support use of the AnalogInputSubsystem.ReferenceTrigger object. To use the ReferenceTrigger object, see page 185.

Some older, legacy devices support continuous about-trigger analog input operations. Use continuous about-trigger mode when you want to continuously acquire data both before and after a specific external trigger occurs. This operation is equivalent to doing both a pre-trigger and a post-trigger acquisition.

To determine if the subsystem supports continuous about-trigger operations, use the AnalogInputSubsystem.SupportsContinuousPrePostTrigger property. If this property returns a value of True, continuous about-trigger mode is supported.

Once you have an AnalogInputSubsystem object, as described on page 146, and set up the channels as described on page 154, set up the AnalogInputSubsystem object for a continuous about-trigger operation as follows:

1. Set the AnalogInputSubsystem.DataFlow property to ContinuousPrePostTrigger.

2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the AnalogInputSubsystem.ChannelType property. See page 201 for more information on channel types.

3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the AnalogInputSubsystem.Encoding property. See page 202 for more information on data encoding.

4. (Optional) Set the voltage range of the subsystem using the AnalogInputSubsystem.VoltageRange property. See page 202 for more information on voltage ranges.

5. (Optional) For measurements that require an excitation source (such as resistance, accelerometers, strain gages, or bridges), set the excitation voltage source for the subsystem using the AnalogInputSubsystem.ExcitationVoltageSource property, and if using an internal excitation source, set the value of the internal excitation voltage source using the AnalogInputSubsystem.ExcitationVoltageValue property. See page 203 for more information on excitation voltage sources.

6. (Optional) For subsystems that allow you to synchronize operations on multiple devices using a synchronization connector, set the synchronization mode of the analog input subsystem on each device using the AnalogInputSubsystem.SynchronizationMode property. See page 203 for more information on synchronization.

7. (Optional) For subsystems that support programmable filter types for measuring temperature, set the filter type using the AnalogInputSubsystem.DataFilterType property. See page 204 for more information.

8. Set up the channel list (including setting the gain and inhibit value for each entry), as described on page 204.
Note: If you want to continuously acquire data from the digital input, counter/timer, tachometer, and/or quadrature decoder channels as part of the analog input stream, you must set up the channel list to include these channels. For counter/timer and quadrature decoder channels, you must also configure and start these subsystems before starting the analog input operation. For digital input ports, you must also configure the digital input subsystem for a single-value operation before starting the analog input operation. Refer to page 230 for information on continuous digital input operations, page 232, page 234, and page 237 for information on continuous counter/timer operations, page 251 for information on tachometer operations, and page 253 for information on quadrature decoder operations.

9. (Optional) Set up the clock, as described on page 212.

10. Use the `AnalogInputSubsystem.Trigger.PreTriggerSource` property to specify the trigger source that starts the pre-trigger operation (generally this is a software trigger).

11. Use the `AnalogInputSubsystem.Trigger.TriggerType` property to specify the external post-trigger source that stops the pre-trigger operation and starts the post-trigger operation. Refer to page 213 for more information on supported trigger sources.

12. If the trigger type is a threshold trigger, do the following:
   a. Specify the channel to use for the threshold trigger using the `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` property. Refer to page 215 for more information.
   b. Specify a voltage value for the threshold level using the `AnalogInputSubsystem.Trigger.Level` property. Refer to page 215 for more information.

13. If supported by your device, set up triggered scan mode, as described on page 227.

14. Set up the input buffers, as described on page 218.

15. If your program is running under a heavy CPU load, it is recommended that you set the `AnalogInputSubsystem.SynchronousBufferDone` property to True for synchronous execution of each BufferDoneEvent event in a single worker thread.

17. Call the `AnalogInputSubsystem.Start` method to start the continuous about-trigger operation.

The about-trigger acquisition begins when the device detects the pre-trigger source. The event PreTriggerBufferDoneEvent is generated as each buffer is filled with pre-trigger analog input data; refer to page 257 for information on dealing with events.

When it detects an external post-trigger source, the device stops acquiring pre-trigger data and starts acquiring post-trigger data. The event BufferDoneEvent is generated as each buffer is filled with post-trigger analog input data. The about-trigger operation continues until either the allocated buffers are filled or you stop the operation.
Figure 4 illustrates continuous about-trigger mode using a channel list of three entries: channel 0, channel 1, and channel 2. In this example, pre-trigger analog input data is acquired on each clock pulse of the A/D sample clock. The device wraps to the beginning of the channel list and the acquisition repeats continuously until the post-trigger event occurs. When the post-trigger event occurs, post-trigger acquisition begins on each clock pulse of the A/D sample clock; refer to page 212 for more information on clock sources. The device wraps to the beginning of the channel list and acquires post-trigger data continuously.

To stop a continuous about-trigger operation, use one of the following methods:

- **AnalogInputSubsystem.Stop** – Stops the operation after the current buffer has been filled. Depending on when the operation was stopped, the driver raises either a PreTriggerBufferDoneEvent or a BufferDoneEvent for the completed buffer and sets the `OlBuffer.ValidSamples` property to the number of samples in the completed buffer. It then raises either a PreTriggerBufferDoneEvent or BufferDoneEvent event for up to eight inprocess buffers, setting the `OlBuffer.ValidSamples` property to 0, before raising a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored. Refer to page 218 for more information on buffers, and to page 257 for information on dealing with events and reading data from the buffers.

- **AnalogInputSubsystem.Abort** – Stops the operation immediately without waiting for the current buffer to be filled and sets the `OlBuffer.ValidSamples` property to the number of samples in the buffer. Depending on when the operation was aborted, the driver raises either a PreTriggerBufferDoneEvent or BufferDoneEvent for up to eight inprocess buffers, setting the `OlBuffer.ValidSamples` property to 0, and then raises a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored.

- **AnalogInputSubsystem.Reset** – Stops the operation immediately without waiting for the current buffer to be filled, and reinitializes the subsystem to the default configuration.

**Figure 4: Continuous About-Trigger Mode**

[Diagram showing the continuous about-trigger mode with channel list and acquisition patterns]
Notes: If you set the `AnalogInputSubsystem.AsynchronousStop` property to True, control returns to your program after `Stop` is called. If you set the `AsynchronousStop` property to False (the default setting) control does not return to your program after `Stop` is called until the buffer completes or 20 seconds elapses (if the buffer takes longer than 20 seconds to fill).

If you try to perform another operation while the stop is in progress, an exception is raised with the error code “SubsystemStopping” and the exception message “The subsystem is in the process of stopping or aborting”.

Continuously Paced Analog Output Operations

Use continuously paced output mode if you want to accurately control the period between conversions of individual analog output channels in the channel list.

To determine if the subsystem supports continuous analog output operations, use the `AnalogOutputSubsystem.SupportsContinuous` property. If this property returns a value of True, the subsystem supports continuously paced analog output operations.

Once you have an `AnalogOutputSubsystem` object, as described on page 146, set up the `AnalogOutputSubsystem` object for a continuous operation as follows:

1. Set the `AnalogOutputSubsystem.DataFlow` property to Continuous.
2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogOutputSubsystem.ChannelType` property. See page 201 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogOutputSubsystem.Encoding` property. See page 202 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the `AnalogOutputSubsystem.VoltageRange` property. See page 202 for more information on voltage ranges.
5. Set up the channel list, as described on page 204.

Note: If you want to continuously update the digital output channels as part of the analog output stream, you must set up the channel list to include the digital output port. In addition, you must configure the digital output subsystem for a single-value operation, as described on page 230, before starting the analog output operation.

6. (Optional) Set up the clock, as described on page 212.
7. (Optional) Use the `AnalogOutputSubsystem.Trigger.TriggerType` property to specify the trigger source that starts the operation. Refer to page 213 for more information on supported trigger sources.
8. If the trigger type is a threshold trigger, do the following:
   a. Specify the channel to use for the threshold trigger using the `AnalogOutputSubsystem.Trigger.ThresholdTriggerChannel` property. Refer to page 215 for more information.
   b. Specify a voltage value for the threshold level using the `AnalogOutputSubsystem.Trigger.Level` property. Refer to page 215 for more information.

9. Set the `AnalogOutputSubsystem.WrapSingleBuffer` property to False (the default value) to specify a buffer wrap mode of none. In this mode, the operation continues indefinitely as long as you process the buffers and put them back on the queue in a timely manner.

10. Use software to fill the output buffer with the values that you want to write to the analog output channels and to the digital output port, if applicable. Refer to page 218 for more information on output buffers.

11. (Optional) For subsystems that allow you to synchronize operations on multiple devices using a synchronization connector, set the synchronization mode of the analog output subsystem on each device using the `AnalogOutputSubsystem.SynchronizationMode` property. See page 203 for more information on synchronization.

13. Call the `AnalogOutputSubsystem.Start` method to start the continuous analog output operation.

When it detects the appropriate trigger, the device starts writing output values to the channels, as determined by the channel list. The operation repeats continuously until either all the data is output from the buffers or you stop the operation. The event BufferDoneEvent occurs as each OlBuffer object is completed. If no buffers are available on the queue, the operation stops, and the event QueueDoneEvent is raised. Refer to page 218 for more information about buffers.

Make sure that the host computer transfers data to the output channel list fast enough so that the list always has data to output; otherwise, the event DriverRunTimeErrorEvent is raised. Refer to page 266 for more information on this event.

If your device supports it, you can mute the output, which attenuates the output voltage to 0 V by calling `AnalogOutputSubsystem.Mute`. This does not stop the analog output operation; instead, the analog output voltage is reduced to 0 V over a hardware-dependent number of samples. You can unmute the output voltage to its current level by calling `AnalogOutputSubsystem.UnMute`. To determine if muting and unmuting are supported by your device, read the value of the `AnalogOutputSubsystem.SupportsMute` property. If this value is True, muting and unmuting are supported.

To stop a continuous analog output operation, do not send new data to the device or use one of the following methods:

- `AnalogOutputSubsystem.Stop` – Stops the operation after all the data in the current buffer has been output. The driver raises a BufferDoneEvent event for the completed buffer and up to eight inprocess buffers, before raising a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored. Refer to page 218 for more information on buffers.
• **AnalogOutputSubsystem.Abort** – Stops the operation immediately without waiting for the data in the current buffer to be output. The driver raises a BufferDoneEvent event for the partially completed buffer and up to eight inprocess buffers, before raising a QueueStoppedEvent event. All subsequent triggers are ignored.

• **AnalogOutputSubsystem.Reset** – Stops the operation immediately without waiting for the data in the current buffer to be output, and reinitializes the subsystem to the default configuration.

**Notes:** If you set the `AnalogOutputSubsystem.AsynchronousStop` property to True, control returns to your program after `Stop` is called. If you set the `AsynchronousStop` property to False (the default setting) control does not return to your program after `Stop` is called until the buffer completes or 20 seconds elapses (if the buffer takes longer than 20 seconds to be output).

If you try to perform another operation while the stop is in progress, an exception is raised with the error code “SubsystemStopping” and the exception message “The subsystem is in the process of stopping or aborting”.

Refer to the example program WriteBufferedDataAsVolts to see how to perform a continuously paced analog output operation.

### Continuous Waveform Generation Operations

Use waveform generation mode if you want to output a waveform repetitively to analog output channels and, if supported, digital output ports, as specified in the ChannelList object.

To determine if the subsystem supports waveform generation operations, use the following properties:

• **AnalogOutputSubsystem.SupportsContinuous** property – If this property returns a value of True, continuous output operations are supported. This is a requirement for waveform generation operations.

• **AnalogOutputSubsystem.SupportsWrapSingle** property – If this property returns a value of True, the device driver will output data continuously from the first buffer queued to the analog output subsystem. This is a requirement for waveform generation operations. Refer to page 218 for more information on buffers.

• **AnalogOutputSubsystem.SupportsWaveformModeOnly** property – If this property returns a value of True, the device driver will output a waveform continuously from the onboard FIFO only. Set the `AnalogOutputSubsystem.WrapSingleBuffer` property to True. In addition, set the buffer size to be less than or equal to the FIFO size specified by the `AnalogOutputSubsystem.FifoSize` property. Refer to page 218 for more information on buffers.
Once you have an AnalogOutputSubsystem object, as described on page 146, set up the AnalogOutputSubsystem object for a continuous operation as follows:

1. Set the `AnalogOutputSubsystem.DataFlow` property to Continuous.

2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogOutputSubsystem.ChannelType` property. See page 201 for more information on channel types.

3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogOutputSubsystem.Encoding` property. See page 202 for more information on data encoding.

4. (Optional) Set the voltage range of the subsystem using the `AnalogOutputSubsystem.VoltageRange` property. See page 202 for more information on voltage ranges.

5. Set up the channel list, as described on page 204.

---

**Note:** If you want to continuously update the digital output channels as part of the analog output stream, you must set up the channel list to include the digital output port. In addition, you must configure the digital output subsystem for a single-value operation, as described on page 230, before starting the analog output operation.

6. (Optional) Set up the clock, as described on page 212.

7. (Optional) Use the `AnalogOutputSubsystem.Trigger.TriggerType` property to specify the trigger source that starts the operation. Refer to page 213 for more information on supported trigger sources.

8. If the trigger type is a threshold trigger, do the following:
   
   a. Specify the channel to use for the threshold trigger using the `AnalogOutputSubsystem.Trigger.ThresholdTriggerChannel` property. Refer to page 215 for more information.

   b. Specify a voltage value for the threshold level using the `AnalogOutputSubsystem.Trigger.Level` property. Refer to page 215 for more information.

9. Set the `AnalogOutputSubsystem.WrapSingleBuffer` property to True, so that a single buffer is reused.

10. Use software to fill the output buffer with the values that you want to write to the analog output channels and to the digital output port, if applicable. Refer to your device documentation for details on the waveform pattern that you can specify and to page 218 for more information on output buffers.
Note: For devices that have a FIFO onboard for waveform generation operations, the device driver downloads the buffer into the FIFO on the device if the size of the buffer is less than or equal to the FIFO size. The driver (or device) outputs the data starting from the first location in the FIFO. When it reaches the end of the FIFO, the driver (or device) continues outputting data from the first location of the FIFO and the process continues indefinitely until you stop it.

You can determine the size of the FIFO on the device using the \texttt{AnalogOutputSubsystem.FifoSize} property. This property returns the actual FIFO size in kilobytes.

11. (Optional) For subsystems that allow you to synchronize operations on multiple devices using a synchronization connector, set the synchronization mode of the analog output subsystem on each device using the \texttt{AnalogOutputSubsystem.SynchronizationMode} property. See page 203 for more information on synchronization.

12. Configure the subsystem using the \texttt{AnalogOutputSubsystem.Config} method.

13. Call the \texttt{AnalogOutputSubsystem.Start} method to start the continuous analog output operation.

When it detects a trigger, the host computer writes the pattern in the buffer to specified output channels, as determined by the channel list.

If your device supports it, you can mute the output, which attenuates the output voltage to 0 V by calling \texttt{AnalogOutputSubsystem.Mute}. This does not stop the analog output operation; instead, the analog output voltage is reduced to 0 V over a hardware-dependent number of samples. You can unmute the output voltage to its current level by calling \texttt{AnalogOutputSubsystem.UnMute}. To determine if muting and unmuting are supported by your device, read the value of the \texttt{AnalogOutputSubsystem.SupportsMute} property. If this value is True, muting and unmuting are supported.

To stop a continuous analog output operation, do not send new data to the device or use one of the following methods:

- \texttt{AnalogOutputSubsystem.Stop} – Stops the operation after all the data in the current buffer has been output. The driver raises a BufferDoneEvent event for the completed buffer and up to eight inprocess buffers, before raising a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored. Refer to page 218 for more information on buffers.

- \texttt{AnalogOutputSubsystem.Abort} – Stops the operation immediately without waiting for the data in the current buffer to be output. The driver raises a BufferDoneEvent event for the partially completed buffer and up to eight inprocess buffers, before raising a QueueStoppedEvent event. All subsequent triggers are ignored.

- \texttt{AnalogOutputSubsystem.Reset} – Stops the operation immediately without waiting for the data in the current buffer to be output, and reinitializes the subsystem to the default configuration.
Notes: If you set the `AnalogOutputSubsystem.AsynchronousStop` property to True, control returns to your program after `Stop` is called. If you set the `AsynchronousStop` property to False (the default setting) control does not return to your program after `Stop` is called until the buffer completes or 20 seconds elapses (if the buffer takes longer than 20 seconds to be output).

If you try to perform another operation while the stop is in progress, an exception is raised with the error code "SubsystemStopping" and the exception message "The subsystem is in the process of stopping or aborting".

Setting the Channel Type

The DT-Open Layers for .NET Class Library supports the following channel types for a specified analog I/O subsystem:

- **SingleEnded** – Use this configuration when you want to measure high-level signals, noise is insignificant, the source of the input is close to the device, and all the input signals are referred to the same common ground.

To determine if the subsystem supports the single-ended channel type, use the `SupportsSingleEnded` property of the appropriate subsystem. If this property returns a value of True, the subsystem supports single-ended inputs.

To determine how many single-ended channels are supported by the subsystem, use the `MaxSingleEndedChannels` property of the appropriate subsystem.

- **Differential** – Use this configuration when you want to measure low-level signals (less than 1 V), you are using an A/D converter with high resolution (greater than 12 bits), noise is a significant part of the signal, or common-mode voltage exists.

To determine if the subsystem supports the differential channel type, use the `SupportsDifferential` property of the appropriate subsystem. If this property returns a value of True, the subsystem supports differential inputs.

To determine how many differential channels are supported by the subsystem, use the `MaxDifferentialChannels` property of the appropriate subsystem.

Set and/or return the channel type using the `ChannelType` property of the appropriate subsystem.

Note: For pseudo-differential analog inputs, specify the single-ended channel type; in this case, how you wire these signals determines the configuration. This option provides less noise rejection than the differential configuration, but twice as many analog input channels.

For older model devices, this setting is jumper-selectable and must be specified in the driver configuration dialog.
Setting the Data Encoding

Two data encoding types are available: binary and twos complement.

To determine if your subsystem supports binary data encoding, use the `SupportsBinaryEncoding` property of the appropriate subsystem. If this property returns a value of True, the subsystem supports binary data encoding.

To determine if your subsystem supports twos complement data encoding, use the `SupportsTwosCompEncoding` property of the appropriate subsystem. If this property returns a value of True, the subsystem supports twos complement data encoding.

Use the `Encoding` property of the appropriate subsystem to specify the data encoding type.

Setting the Voltage Range

To determine how many ranges the subsystem supports, use the `NumberOfRanges` property of the appropriate subsystem.

To determine all the available voltage ranges for your subsystem, use the `SupportedVoltageRanges` property of the appropriate subsystem.

Some analog output subsystems support both voltage and current output channels. To determine if the subsystem supports current outputs, use the `AnalogOutputSubsystem.SupportsCurrentOutput` property.

Use the `VoltageRange` property of the appropriate subsystem to set or return the voltage range for the subsystem.

**Note:** If you are using a current output channel, determine how the voltage range maps to your current output range and write the appropriate voltage to the output channel.

The following example shows how to set the voltage range for an analog input subsystem to the first range in the list of supported voltage ranges:

**Visual C#**
```
ainSS.VoltageRange = ainSS.SupportedVoltageRanges[0];
```

**Visual Basic**
```
ainSS.VoltageRange = ainSS.SupportedVoltageRanges(0)
```
Setting the Excitation Voltage Source and Value

To determine if the analog input subsystem supports an internal excitation voltage source, use the `AnalogInputSubsystem.SupportsInternalExcitationVoltageSrc` property. To determine if the analog input subsystem supports an external excitation voltage source, use the `AnalogInputSubsystem.SupportsExternalExcitationVoltageSrc` property.

You specify the excitation voltage source to use (Internal, External, or Disabled) for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property. By default, the excitation voltage source is disabled.

If you set the excitation voltage source to Internal, you can also set the value of the excitation voltage source using the `SupportedChannelInfo.ExcitationVoltageValue` property.

You can determine the minimum allowable value for the internal excitation voltage source using the `AnalogInputSubsystem.MinExcitationVoltageValue` property. Similarly, you can determine the maximum allowable value for the internal excitation voltage source using the `AnalogInputSubsystem.MaxExcitationVoltageValue` property.

Setting the Synchronization Mode

Some devices provide one or more synchronization connectors (such as an LVDS RJ45 or Sync Bus connector) that allows you to synchronize operations on multiple devices. In this configuration, the subsystem on one device is configured as the master and the subsystem on the other device is configured as a slave. When the subsystem on the master module is triggered, the specified subsystem on both the master device and the slave device start operating at the same time.

To determine if your subsystem supports the ability to program the synchronization mode, use the `SupportsSynchronization` property of the appropriate subsystem.

If the subsystem supports programmable synchronization modes, use the `SynchronizationMode` property to set or get the current synchronization mode; the following values are supported:

- None – The subsystem is configured to ignore the synchronization circuit.
- Master – Sets the subsystem as a master; the synchronization connector on the device is configured to output a synchronization signal.
- Slave – Sets the subsystem as a slave; the synchronization connector on the device is configured to accept a synchronization signal as an input.

Refer to your hardware documentation for more information on how synchronization works for your device.
Setting the Filter Type

For some devices, like the TEMPpoint and VOLTpoint instruments, that support programmable filter types for measuring data, you can set the filter type.

To determine if your subsystem supports the ability to program the filter type, use the \texttt{SupportsDataFilters} property of the appropriate subsystem.

If the subsystem supports programmable filter types, use the \texttt{DataFilterType} property to set or get the current filter type; the following values are supported:

- \textbf{Raw} – No filter. Provides fast response times, but the data may be difficult to interpret. Use when you want to filter the data yourself.
  
  The Raw filter type returns the data exactly as it comes out of the Delta-Sigma A/D converters. Note that Delta-Sigma converters provide substantial digital filtering above the Nyquist frequency.

  Generally, the only time it is desirable to use the Raw filter type is if you are using fast responding inputs, sampling them at higher speeds (> 1 Hz), and need as much response speed as possible.

- \textbf{MovingAverage} – Provides a compromise of filter functionality and response time. This filter can be used in any application. This low-pass filter takes the previous 16 samples, adds them together, and divides by 16.

\textbf{Note:} The properties \texttt{SupportsTemperatureFilters} and \texttt{TemperatureFilterType} are deprecated properties that have been replaced by \texttt{SupportsDataFilters} and \texttt{DataFilterType}, respectively.

Setting up the Channel List

\textbf{Note:} Single-value operations do not use a channel list.

If you want to acquire data from or update multiple channels, you need to use a continuous operation mode and specify the channels that you want to sample (and the order in which to sample them) in a ChannelList object.

Channels are sampled or updated in order from the first entry to the last entry in the ChannelList object. Channel numbering is zero-based; that is, the first entry in the ChannelList is at index 0, the second entry is at index 1, and so on.

The ChannelList property is accessible using any subsystem class whose \texttt{SupportsContinuous} property is True. Typically, a ChannelList is used with the AnalogInputSubsystem and AnalogOutputSubsystem classes.
For an analog input subsystem, you can specify analog input channels, as well as digital inputs, counter/timers, and/or quadrature decoders in the ChannelList object, if your device supports it. Similarly, for an analog output subsystem, you can specify analog output channels as well as digital outputs in the ChannelList object, if your device supports it. Refer to page 150 for more information on available channels.

You can add sequential channels (such as channels 0, 1, 2, 3) or random channels (such as channels 2, 9, 7) to the ChannelList object, and can specify a channel more than once in the list (such as channels 1, 2, 1), if your device supports it.

For devices that support simultaneous sample-and-hold mode, the channel numbers must typically be in ascending order (such as 3, 6, 8, and so on), and cannot be repeated. To determine if the subsystem supports simultaneous sample-and-hold mode, use the AnalogInputSubsystem.SupportsSimultaneousSampleHold property. If this property returns a value of True, the subsystem supports simultaneous sample-and-hold mode.

Other devices may limit the order in which you can enter a channel in the channel list. See the user’s manual for your device to determine any channel ordering limitations.

The following example shows a ChannelList that contains four channels. Channel 1 is sampled first, followed by channel 2, channel 1 again, and then channel 0:

<table>
<thead>
<tr>
<th>Channel-List Index</th>
<th>Channel</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>Sample channel 1.</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>Sample channel 2.</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>Sample channel 1 again.</td>
</tr>
<tr>
<td>3</td>
<td>0</td>
<td>Sample channel 0.</td>
</tr>
</tbody>
</table>

**Adding Channels to a Channel List**

The ChannelList.Add method adds a channel to the end of the ChannelList object, and returns the index of the added channel. You can specify the channel to add in one of the following ways:

- By physical channel number
- By channel name
- By ChannelListEntry object

The following sections describe these methods.
Adding Channels By Physical Channel Number

This method is the simplest way to add channels into the ChannelList object, particularly if you are adding channels that are native to the subsystem type (such as analog input channels on an analog input subsystem).

For native channels, the physical channel number always equals the logical channel number. While non-native channels, such as digital inputs that are streamed through the analog input subsystem, can also be added this way, the physical channel number is not the same as the logical channel number, so you may find it easier to add the channel by name or by ChannelListEntry object instead.

A new ChannelListEntry object is returned for each physical channel that is added this way. Refer to page 208 for more information on ChannelListEntry objects.

The following example shows how to use the `Add` method to add physical channel 0 to the end of a ChannelList for an analog input subsystem:

**Visual C#**

```csharp
ch = AinSS.ChannelList.Add(0);
```

**Visual Basic**

```vbnet
ch = AinSS.ChannelList.Add(0)
```

Adding Channels By Channel Name

The channel name is the name that you assigned to the channel using the SupportedChannelInfo class, described on page 150. A new ChannelListEntry object is returned for each channel that is added this way. Refer to page 208 for more information on ChannelListEntry objects.

The following example shows how to use the `Add` method to add a channel named Sensor to the end of a ChannelList for an analog input subsystem:

**Visual C#**

```csharp
//Specify the name Sensor for the first analog input channel.
ainSS.SupportedChannels[0].Name = "Sensor";
//Add the channel named Sensor to the ChannelList
ch = ainSS.ChannelList.Add("Sensor");
```

**Visual Basic**

```vbnet
'Specify the name Sensor for the first analog input channel.
ainSS.SupportedChannels(0).Name = "Sensor"
ch = AinSS.ChannelList.Add("Sensor")
```
Adding Channels By ChannelListEntry Object

This method is useful if you want a more generic approach to adding channels. This approach frees you from keeping track of physical channel numbers and their names.

To get a ChannelListEntry object, use the ChannelListEntry constructor within the ChannelListEntry class, specifying the SupportedChannelInfo object for the channel that you want to sample or update. See page 150 for more information on SupportedChannelInfo objects.

This example creates a ChannelListEntry called Ch0 for physical channel 0 of the analog input subsystem, using all the information contained in SupportedChannelInfo for that channel.

**Visual C#**

```csharp
ChannelListEntry Ch0 = new ChannelListEntry(
    ainSS.SupportedChannels.GetChannelInfo
    (SubsystemType.AnalogInput, 0));
```

**Visual Basic**

```vbnet
Dim Ch0 As New ChannelListEntry(
    ainSS.SupportedChannels.GetChannelInfo
    (SubsystemType.AnalogInput, 0))
```

**Note:** It is recommended that you set the gain (see page 210) and inhibition value (page 211) for each ChannelListEntry object after you create it. However, it is possible to set or change these values after the ChannelListEntry object is added to the ChannelList.

The following example shows how to use the Add method to add ChannelListEntry object Ch0 to the end of a ChannelList:

**Visual C#**

```csharp
AinSS.ChannelList.Add(Ch0);
```

**Visual Basic**

```vbnet
AinSS.ChannelList.Add(Ch0)
```

Inserting Channels in the Channel List

The ChannelList.Insert method inserts a channel at the specified index of a ChannelList object, incrementing all higher index entries by 1, and returns the index of the added channel. You can specify the channel to insert in one of the following ways:

- By physical channel number
- By channel name
- By ChannelListEntry object

The following sections describe these methods.
Inserting a Channel By Physical Channel Number

This method is the simplest way to insert channels into the ChannelList object, particularly if you are inserting channels that are native to the subsystem type (such as analog input channels on an analog input subsystem).

For native channels, the physical channel number always equals the logical channel number. While non-native channels, such as digital inputs that are streamed through the analog input subsystem, can also be inserted this way, the physical channel number is not the same as the logical channel number, so you may find it easier to insert the channel by name or by ChannelListEntry object instead.

A new ChannelListEntry object is returned for each physical channel that is inserted this way. Refer to page 208 for more information on ChannelListEntry objects.

The following example shows how to use the Insert method to insert physical channel 3 at index 0 of the ChannelList for an analog input subsystem. The channel that was formally at index 0 is now at index 1.

**Visual C#**

```csharp
ch = AinSS.ChannelList.Insert(0, 3);
```

**Visual Basic**

```vbnet
ch = AinSS.ChannelList.Insert(0, 3)
```

Inserting a Channel By Channel Name

The channel name is the name that you assigned to the channel using the SupportedChannelInfo class, described on page 150. A new ChannelListEntry object is returned for each channel that is inserted this way. Refer to page 208 for more information on ChannelListEntry objects.

The following example shows how to use the Insert method to insert a channel named Ain3 at index 0 of the ChannelList for an analog input subsystem. The channel that was formally at index 0 is now at index 1.

**Visual C#**

```csharp
ch = AinSS.ChannelList.Insert(0, "Ain3");
```

**Visual Basic**

```vbnet
ch = AinSS.ChannelList.Insert(0, "Ain3")
```

Inserting a Channel By ChannelListEntry Object

This method is useful if you want a more generic approach to inserting channels. This approach frees you from keeping track of physical channel numbers and their names.

To get a ChannelListEntry object, use the ChannelListEntry constructor within the ChannelListEntry class, specifying the SupportedChannelInfo object for each channel that you want to sample or update. See page 150 for more information on SupportedChannelInfo objects.
This example creates a ChannelListEntry called Ch3 for physical channel 3 of the analog input subsystem, using all the information contained in SupportedChannelInfo for that channel.

**Visual C#**

```csharp
ChannelListEntry Ch3 = new ChannelListEntry {
    ainSS.SupportedChannels.GetChannelInfo
    (SubsystemType.AnalogInput, 3 )
};
```

**Visual Basic**

```vbnet
Dim Ch3 As New ChannelListEntry {
    ainSS.SupportedChannels.GetChannelInfo
    (SubsystemType.AnalogInput, 3 )
}
```

**Note:** It is recommended that you set the gain (see page 210) and inhibition value (page 211) for each ChannelListEntry object after you create it. However, it is possible to set or change these values after the ChannelListEntry object is added to the ChannelList.

The following example shows how to use the `Insert` method to insert ChannelListEntry object Ch3 at index 0 of the ChannelList. The channel that was formally at index 0 is now at index 1.

**Visual C#**

```csharp
AinSS.ChannelList.Insert(0, Ch3);
```

**Visual Basic**

```vbnet
AinSS.ChannelList.Insert(0, Ch3)
```

**Replacing Channels in the ChannelList**

The ChannelList.Item ([]) property replaces a ChannelListEntry object at the specified index of the ChannelList. An exception is raised if an entry does not exist at the specified index.

The following example shows how to use the Item ([]) property to replace the ChannelListEntry object at index 1 of the ChannelList with ChannelListEntry object Ch3:

**Visual C#**

```csharp
AinSS.ChannelList[1] = Ch3;
```

**Visual Basic**

```vbnet
AinSS.ChannelList(1) = Ch3
```
Removing Channels from the Channel List

To remove a ChannelListEntry from the ChannelList object, use the `ChannelList.Remove` method. This method removes the first instance of the specified ChannelListEntry object from the ChannelList object, decrementing all higher index entries by 1.

The following example shows how to remove the first instance of ChannelListEntry object Ch0 from the ChannelList object using the `Remove` method:

```csharp
AinSS.ChannelList.Remove(Ch0);
```

```vbnet
AinSS.ChannelList.Remove(Ch0)
```

Setting the Gain of a ChannelListEntry

The voltage range divided by the gain determines the effective range for a channel. For example, if your device provides a voltage range of ±10 V and you want to measure a ±1.5 V signal, specify a range of ±10 V and a gain of 4; the effective input range for this channel is then ±2.5 V (±10/4), which provides the best sampling accuracy for that channel.

To determine if the subsystem supports programmable gain, use the `SupportsProgrammableGain` property of the appropriate subsystem. If this property returns a value of True, programmable gain is supported.

To determine the number of gains the subsystem supports, use the `NumberofSupportedGains` property of the appropriate subsystem. To list all of the gain values supported by the subsystem, use the `SupportedGains` property.

The simplest way to specify the gain for a channel is by using a single-value operation. (In this case, a ChannelListEntry object is not used.) Refer to page 176 for more information on single-value analog input operations; refer to page 180 for more information on single-value analog output operations.

If you are using a ChannelListEntry object, specify or return the gain for each ChannelListEntry object using the `ChannelListEntry.Gain` property.

This example shows how to apply a gain of 2 to a ChannelListEntry called Ch0.

```csharp
Ch0.Gain = 2;
```

```vbnet
Ch0.Gain = 2
```

You can also apply gain to a ChannelListEntry in the ChannelList, as shown below; this example applies a gain of 2 to the ChannelListEntry at index 0 of the ChannelList:

```csharp
AinSS.ChannelList[0].Gain = 2;
```
**Visual Basic**

AinSS.ChannelList(0).Gain = 2

---

**Note:** The driver sets the actual gain as closely as possible to the number specified. You can read back the exact gain after configuring the subsystem using the **Gain** property. If your subsystem does not support programmable gain, enter a value of 1 (the default value) for the gain.

---

### Inhibiting Channels in a Channel List

If supported by your subsystem, you can inhibit data from being returned by the ChannelListEntry object. This feature is useful if you want to discard values that are acquired by specific channels.

To determine if a subsystem supports inhibition, use the **SupportsChannelListInhibit** property inherited from the SubsystemBase class. If this property returns a value of True, the subsystem supports channel inhibition.

Using the **Inhibit** property of the ChannelListEntry class, you can enable or disable inhibition for each ChannelListEntry object. If you set this property to True, the acquired value is discarded after the channel entry is sampled. If you set this property to False (the default value), the acquired value is stored after the channel entry is sampled.

This example shows how to set the channel inhibit value of the ChannelListEntry called Ch0 to True:

**Visual C#**

```csharp
Ch0.Inhibit = 1;
```

**Visual Basic**

```vbnet
Ch0.Inhibit = 1
```

You can also set the inhibit value of a ChannelListEntry in the ChannelList, as shown below; this example sets the inhibit value to True for the ChannelListEntry at index 3 of the ChannelList:

**Visual C#**

```csharp
AinSS.ChannelList[3].Inhibit = 1;
```

**Visual Basic**

```vbnet
AinSS.ChannelList(3).Inhibit = 1
```
Getting Information about Channels in the ChannelList Object

You can get information about the contents of a ChannelList object using the following methods:

- `ChannelList.Contains` method – Determines whether a specified ChannelListEntry object is contained in the ChannelList.
- `ChannelList.IndexOf` method – Searches for a specified channel (specified by physical channel or ChannelListEntry object) in the ChannelList and returns the zero-based index of the first occurrence within the ChannelList.
- `ChannelList.CGLDepth` property – Returns the maximum number of channels or ChannelListEntry objects that the ChannelList can contain.

Setting up a Clock Source

The DT-Open Layers for .NET Class Library defines internal and external clock sources, described in the following subsections. Note that single-value operations do not use clocks.

**Note:** Some subsystems allow you to read or update multiple channels on a single clock pulse. You can determine whether multiple channels are read or updated on a single clock pulse by using the `Clock.SupportsSimultaneousClocking` property.

In addition, some subsystems support different clock frequencies depending on whether the device is powered by an internal power source or an external power source. To determine if your device supports an internal power source or an external power source, use the `PowerSource` property inherited from the SubsystemBase class.

Internal Clock Source

The internal clock is the clock source on the device that paces data acquisition or output for each ChannelListEntry object in the channel list.

To determine if the subsystem supports an internal clock, use the `Clock.SupportsInternalClock` property. If this property returns a value of True, an internal clock is supported.

To determine the maximum frequency supported by the internal clock, use the `Clock.MaxFrequency` property. To determine the minimum frequency supported by the internal clock, use the `Clock.MinFrequency` property.

Specify the clock source as internal using the `Clock.Source` property. Then, use the `Clock.Frequency` property to specify the frequency at which to pace the operation.
Note: According to sampling theory (Nyquist Theorem), you should specify a frequency for an A/D signal that is at least twice as fast as the input’s highest frequency component. For example, to accurately sample a 20 kHz signal, specify a sampling frequency of at least 40 kHz. Doing so avoids an error condition called aliasing, in which high frequency input components erroneously appear as lower frequencies after sampling.

The driver sets the frequency of the internal clock as close as possible to the value that you specified in the Frequency property. You can determine the actual frequency that was set on the hardware by reading the value of the Frequency property after the subsystem has been configured (using the Config method).

**External Clock Source**

The external clock is a clock source attached to the device that paces data acquisition or output for each channel in the channel list. This clock source is useful when you want to pace at rates not available with the internal clock or if you want to pace at uneven intervals.

To determine if the subsystem supports an external clock, use the Clock.SupportsExternalClock property. If this property returns a value of True, an external clock is supported.

To determine the maximum external clock divider that the subsystem supports, use the Clock.MaxExtClockDivider property. To determine the minimum external clock divider that the subsystem supports, use the Clock.MinExtClockDivider property.

Specify the clock source as external using the Clock.Source property. Then, use the Clock.ExtClockDivider property to set or get the clock divider that is used to determine the frequency of the external clock source. The frequency of the external clock input divided by the external clock divider determines the frequency at which to pace the operation.

**Setting Up a Trigger Type**

Note: Single-value operations do not use triggers.

The DT-Open Layers for .NET Class Library provides the Trigger class that can be used to set up a start trigger, and the ReferenceTrigger class that can be used to set up a reference trigger, if supported by your device. The following trigger types are available for the start and reference triggers:

- Software
- TTLPos
- TTLNeg
- ThresholdPos
• ThresholdNeg
• DigitalEvent

For devices that support a start trigger and reference trigger for performing continuous pre-and post-trigger analog input operations, specify the start trigger type using the `AnalogInputSubsystem.Trigger.TriggerType` property and specify the reference trigger type using the `AnalogInputSubsystem.ReferenceTrigger.TriggerType` property; refer to page 185 for more information on pre- and post-trigger operations using a start and reference trigger.

For devices that support continuous post-trigger and about-trigger operations without using a reference trigger, specify the post-trigger source using the `AnalogInputSubsystem.Trigger.TriggerType` property; refer to page 187 for more information on post-trigger operations and page 193 for more information on about-trigger operations.

For legacy devices that support a pre-trigger source without using a reference trigger, use the `AnalogInputSubsystem.Trigger.PreTriggerSource` property of the Trigger class; see page 190 for more information on pre-trigger operations. To specify a retrigger source, use the `AnalogInputSubsystem.TriggeredScan.RetriggerSource` property; see page 228 for more information on retriggers.

The following subsections describe these trigger sources. Note that you cannot specify a trigger source for single-value operations.

**Software Trigger Source**

A software trigger occurs when you start the operation; internally, the computer writes to the device to begin the operation.

To determine if the subsystem supports a software trigger for the start trigger, use the `Trigger.SupportsSoftwareTrigger` property. If this property returns a value of True, a software trigger is supported.

To determine if the subsystem supports a software trigger for the reference trigger, use the `ReferenceTrigger.SupportsSoftwareTrigger` property. If this property returns a value of True, a software trigger is supported.

**TTLPos Trigger Source**

The TTLPos trigger source is an external digital (TTL) signal attached to the device. The trigger occurs when the device detects a transition on the rising edge of the digital TTL signal.

To determine if the subsystem supports a TTLPos trigger for a start trigger, use the `Trigger.SupportsPosExternalTTLTrigger` property. If this property returns a value of True, a TTLPos trigger is supported.

To determine if the subsystem supports a TTLPos trigger for a reference trigger, use the `ReferenceTrigger.SupportsPosExternalTTLTrigger` property. If this property returns a value of True, a TTLPos trigger is supported.
To determine if the subsystem supports a TTLPos trigger for a single-value operation, use the `Trigger.SupportsSvPosExternalTTLTrigger` property. If this property returns a value of True, a TTLPos trigger is supported.

**TTLNeg Trigger Source**

The TTLNeg trigger source is an external digital (TTL) signal attached to the device. The trigger occurs when the device detects a transition on the falling edge of the digital TTL signal.

To determine if the subsystem supports a TTLNeg trigger for a start trigger, use the `Trigger.SupportsNegExternalTTLTrigger` property. If this property returns a value of True, a TTLNeg trigger is supported.

To determine if the subsystem supports a TTLNeg trigger for a reference trigger, use the `ReferenceTrigger.SupportsNegExternalTTLTrigger` property. If this property returns a value of True, a TTLNeg trigger is supported.

To determine if the subsystem supports a TTLNeg trigger for a single-value operation, use the `Trigger.SupportsSvNegExternalTTLTrigger` property. If this property returns a value of True, a TTLNeg trigger is supported.

**ThresholdPos Trigger Source**

A threshold trigger is generally either an analog signal from an analog input channel or an external analog signal attached to the device. A positive analog threshold (ThresholdPos) trigger occurs when the device detects a positive-going signal that crosses a threshold value.

To determine if the subsystem supports a ThresholdPos trigger for the start trigger, use the `Trigger.SupportsPosThresholdTrigger` property. If this property returns a value of True, a ThresholdPos trigger is supported.

To determine if the subsystem supports a ThresholdPos trigger for the reference trigger, use the `ReferenceTrigger.SupportsPosThresholdTrigger` property. If this property returns a value of True, a ThresholdPos trigger is supported.

To determine which channels support a threshold trigger for the start trigger, use the `Trigger.SupportedThresholdTriggerChannels` property. To set the channel that you want to use for the threshold start trigger, use the `Trigger.ThresholdTriggerChannel` property.

To determine which channels support a threshold trigger for the reference trigger, use the `ReferenceTrigger.SupportedThresholdTriggerChannels` property. To set the channel that you want to use for the threshold reference trigger, use the `ReferenceTrigger.ThresholdTriggerChannel` property.

On some devices, the threshold level is set using an analog output subsystem on the device. On other devices, you set the threshold level using the `Trigger.Level` property (for the start trigger) or `ReferenceTrigger.Level` property (for the reference trigger). By default, the trigger threshold value is in voltage unless specified otherwise for the device; see the user’s manual for your device for valid threshold value settings.
Note: The threshold level set by the Trigger.Level or ReferenceTrigger.Level property depends on the voltage range and gain of the subsystem. For example, if the voltage range of the analog input subsystem is ±10 V, and the specified gain is 1, specify a threshold voltage level within ±10 V. Likewise, if the voltage range of the analog input subsystem is ±10 V, and the specified gain is 10, specify a threshold voltage level within ±1 V. Refer to your device documentation for details on how to specify the threshold value for your device.

**ThresholdNeg Trigger Source**

A threshold trigger is generally either an analog signal from an analog input channel or an external analog signal attached to the device. A negative analog threshold trigger (ThresholdNeg) occurs when the device detects a negative-going signal that crosses a threshold value.

To determine if the subsystem supports a ThresholdNeg trigger for the start trigger, use the Trigger.SupportsNegThresholdTrigger property. If this property returns a value of True, a ThresholdNeg trigger is supported.

To determine if the subsystem supports a ThresholdNeg trigger for the reference trigger, use the ReferenceTrigger.SupportsNegThresholdTrigger property. If this property returns a value of True, a ThresholdNeg trigger is supported.

To determine which channels support a threshold trigger for the start trigger, use the Trigger.SupportedThresholdTriggerChannels property. To set the channel that you want to use for the threshold start trigger, use the Trigger.ThresholdTriggerChannel property.

To determine which channels support a threshold trigger for the reference trigger, use the ReferenceTrigger.SupportedThresholdTriggerChannels property. To set the channel that you want to use for the threshold reference trigger, use the ReferenceTrigger.ThresholdTriggerChannel property.

On some devices, the threshold level is set using an analog output subsystem on the device. On other devices, you set the threshold level using the Trigger.Level property (for the start trigger) or the ReferenceTrigger.Level property (for the reference trigger). By default, the trigger threshold value is in voltage unless specified otherwise for the device; see the user’s manual for your device for valid threshold value settings.

Note: The threshold level set by the Trigger.Level or ReferenceTrigger.Level property depends on the voltage range and gain of the subsystem. For example, if the voltage range of the analog input subsystem is ±10 V, and the specified gain is 1, specify a threshold voltage level within ±10 V. Likewise, if the voltage range of the analog input subsystem is ±10 V, and the specified gain is 10, specify a threshold voltage level within ±1 V. Refer to your device documentation for details on how to specify the threshold value for your device.
**DigitalEvent Trigger Source**

For a DigitalEvent trigger source, a trigger is generated when an external digital event occurs.

To determine if the subsystem supports a DigitalEvent trigger for the start trigger, use the `Trigger.SupportsDigitalEventTrigger` property. If this property returns a value of True, a DigitalEvent trigger is supported.

To determine if the subsystem supports a DigitalEvent trigger for the reference trigger, use the `ReferenceTrigger.SupportsDigitalEventTrigger` property. If this property returns a value of True, a DigitalEvent trigger is supported.

**Sync Bus Trigger Source**

For devices that support connecting multiple devices together in a master/slave relationship using Sync Bus (RJ45) connectors, the slave device may support the ability to configure a Sync Bus trigger source as the reference trigger.

To determine if the subsystem supports a Sync Bus trigger source as the reference trigger, use the `ReferenceTrigger.SupportsSyncBusTrigger` property. If this property returns a value of True, a Sync Bus trigger is supported.

Use the Sync Bus trigger source as the reference trigger if you want the slave device to receive a Sync Bus trigger from one of the other devices to stop pre-trigger acquisition and start post-trigger acquisition.

If you want to set the slave module to receive a Sync Bus trigger as the start trigger source, set the synchronization mode of the device to Slave using the `SynchronizationMode` property of for the subsystem, described on page 203; the Sync Bus trigger is used by the slave module as the start trigger source by default.

**Setting up a Post-Trigger Scan Count**

On devices that support a reference trigger for performing continuous pre- and post-trigger analog input operations, you can specify how many samples to acquire after the reference trigger occurs using the `AnalogInputSubsystem.ReferenceTrigger.PostTriggerScanCount` property.

To determine if your device supports the ability to specify the number of post-trigger samples to acquire, use the `AnalogInputSubsystem.ReferenceTrigger.SupportsPostTriggerScanCount` property.
Chapter 3

Setting up Buffers

**Note:** Single-value operations do not use buffers.

Continuous analog input and analog output operations require buffers in which to store data. For input operations, a queue exists to hold the buffers that are empty and ready for input. For output operations, the queue holds buffers that you have filled with data and are ready for output.

To determine if the subsystem supports buffering, use the `SupportsBuffering` property within the appropriate subsystem class. If this property returns a value of True, buffering is supported.

If you want to acquire one buffer of data from one channel using a continuous analog input operation, use the `AnalogInputSubsystem.GetOneBuffer` method; this method allocates an `OlBuffer` object of the size you specify and acquires one buffer of data for you.

For all other operations, use the `OlBuffer` constructor within the `OlBuffer` class to create an `OlBuffer` object for use with an analog input or analog output subsystem. The library automatically allocates an internal data buffer, which is encapsulated by the `OlBuffer` object. You specify the subsystem with which to associate the `OlBuffer` object as well the size (in samples) of the internal buffer to allocate.

If desired, you can use the `OlBuffer.Tag` property, if desired, to name the buffer with the contents that are contained in the buffer.

**Note:** If you use the `ReturnCjcTemperaturesInStream` property, described on page 159, to return CJC data in the data stream, ensure that you set the size of the internal buffer to be twice as large to accommodate the returned CJC values for each channel (number of samples per channel x 2).

If you set the size of the internal buffer that is encapsulated by an `OlBuffer` object and later you want to change the size, call the `OlBuffer.Reallocate` method. This method reallocates the internal buffer to the specified number of samples; the initial internal buffer is deallocated and any data that it contained is lost.

The `AnalogInputSubsystem.GetOneBuffer` method uses one buffer. Other continuous analog input operations require a minimum of two `OlBuffer` objects. Continuous analog output operations require a minimum of two `OlBuffer` objects if `WrapSingleBuffer` is False; if `WrapSingleBuffer` is True, one `OlBuffer` object is required.

Once you have created the `OlBuffer` objects for multiple buffer operations (and, for output operations, filled the corresponding internal buffers with data), put the `OlBuffer` objects on the queue using the `BufferQueue.QueueBuffer` method of the appropriate subsystem.
The following example shows how to create multiple OlBuffer objects for a continuous analog input operation and put them on the queue for the analog input subsystem. In this example, an internal buffer of 1024 samples is allocated when the OlBuffer object is created:

**Visual C#**

```csharp
// Create the buffers
for (int i=0; i<4; ++i)
{
    AinBuffer[i] = new OlBuffer (1024, ainSS);
    // Put the buffers on the queue
    ainSS.BufferQueue.QueueBuffer (AinBuffer[i]);
}
```

**Visual Basic**

```vb
While i < 4
    ' Create the buffers
    AinBuffers(i) = New OlBuffer(1024, ainSS)
    ' Put the buffers on the queue
    ainSS.BufferQueue.QueueBuffer(AinBuffers(i))
    i += 1
End While
```

When you start a continuous operation, the device takes up to eight OlBuffer objects from the subsystem queue and begins filling them (for input operations) or outputting data from them (for output operations) at the specified clock rate. The state of these objects changes from queued to inprocess.

**About QueuedCount and InProcessCount**

You can determine the number of OlBuffer objects that are on the subsystem queue by using the `BufferQueue.QueuedCount` property. You can determine the number of OlBuffer objects that are inprocess by using the `BufferQueue.InProcessCount` property.

Every time an OlBuffer object transitions from the queued state to the inprocess state, the value of the `QueuedCount` property decreases by 1 and the value of the `InProcessCount` property increases by 1. For example, assume that you call `QueueBuffer` for 10 OlBuffer objects; the `QueuedCount` is 10 and the `InProcessCount` is 0. Once you call `Start` for the subsystem, up to 8 OlBuffer objects are moved from the queued state to the inprocess state. `QueuedCount` is now 2 and `InProcessCount` is 8.

If you do not put the OlBuffer objects back on the queue as they are completed, the `QueuedCount` decreases while the `InProcessCount` remains the same (as a new inprocess buffer replaces a completed buffer) until the `QueuedCount` gets to 0, then the `InProcessCount` starts decreasing until all the OlBuffer objects are completed, as shown below:
Buffer Completion Events

Note: Buffer completion events are not generated if you use the \texttt{AnalogInputSubsystem.GetOneBuffer} method. This is a synchronous method that does not return until the buffer has been acquired or the timeout value has expired.

One or more of the following events is generated when a buffer is completed:

- \textbf{BufferDoneEvent} – For input operations, this event is generated when the internal buffer of the \texttt{OlBuffer} object has been filled with post-trigger data. For output operations, this event is generated when all the data in the internal buffer of the \texttt{OlBuffer} object has been output. Refer to page 259 for more information on this event.

- \textbf{PreTriggerBufferDoneEvent} – For input operations only, this event is generated when the internal buffer of the \texttt{OlBuffer} object has been filled with pre-trigger data. Refer to page 261 for more information on this event.

- \textbf{QueueStoppedEvent} – This event occurs when you stop a continuous analog I/O operation with \texttt{Stop} or \texttt{Abort}. Refer to page 262 for more information on this event.

\end{table}
• **IOCompleteEvent** – For analog input operations that use a reference trigger whose trigger type is something other than software (none), this event occurs when the last post-trigger sample is copied into the user buffer; devices that do not support a reference trigger will never receive this event for analog input operations.

For analog output operations, this event is generated when the last data point has been output from the analog output channel. Refer to page 263 for more information on this event.

• **QueueDoneEvent** – This event is generated when no OlBuffer objects are available on the queue and the operation stops. Refer to page 265 for more information on this event.

**Handling Input Buffers**

Each time a BufferDoneEvent or PreTriggerBufferDoneEvent event is raised, your application program must handle the event or you will lose the data in the internal buffer of the OlBuffer object. Refer to page 257 for more information about handling events and buffers.

You can post-process OlBuffer objects, if you wish. One technique for doing this is to allocate an array that will hold the OlBuffer objects as they are completed. When the BufferDoneEvent or PreTriggerBufferDoneEvent event occurs, move the OlBuffer object into a array. When the operation is complete, process the OlBuffer objects in your array.

For continuous analog input operations, use one of the following methods to copy the data from the internal buffer of an OlBuffer object into a user-declared array/variable (the data type of this array/variable is dictated by the method/property you choose):

**Note:** For ease of use, all of these methods allocate the returned array to the correct size. Simply declare an array of the appropriate type for use with one these methods.

• **OlBuffer.GetDataAsRawByte** – Copies the data, as raw counts, from the internal buffer of the OlBuffer object into a user-declared array of bytes. You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

To use this method, first declare an array of bytes.

**Note:** This method is useful when writing binary data to a file. Since each sample takes more than one array entry, other uses may be limited.

• **OlBuffer.GetDataAsRawInt16** – Used when the resolution of the subsystem is 16 bits or less and when the data encoding is twos complement, copies the data, as raw counts, from the internal buffer of the OlBuffer object into a user-declared array of signed, 16-bit integers (short). You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.
To use this method, first declare an array of signed, 16-bit integers (short).

- **OlBuffer.GetDataAsRawUInt16** – Used when the resolution of the subsystem is 16 bits or less and when the data encoding is binary, copies the data, as raw counts, from the internal buffer of the OlBuffer object into a user-declared array of unsigned, 16-bit integers (ushort). You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.
  
  To use this method, first declare an array of unsigned, 16-bit integers (ushort).

- **OlBuffer.GetDataAsRawUInt32** – Used when the resolution of the subsystem is greater than 16 bits, copies the data, as raw counts, from the internal buffer of the OlBuffer object into a user-declared array of unsigned 32-bit integers (uint). You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.
  
  To use this method, first declare an array of unsigned, 32-bit integers (uint).

- **OlBuffer.GetDataAsSensor** – Converts the data from the internal buffer of the OlBuffer object into sensor values using the specified sensor gain and offset (described on page 156), and copies this data into a user-declared array of 64-bit floating-point values (double). You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.
  
  To use this method, first declare an array of 64-bit floating-point (double) values.

- **OlBuffer.GetDataAsVolts** – Converts the data from the internal buffer of the OlBuffer object into voltages, and copies this data into a user-declared array of 64-bit floating-point (double) values. You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.
  
  To use this method, first declare an array of 64-bit floating-point (double) values.

  **Note:** If the `AnalogInputSubsystem.ReturnCjcTemperaturesInStream` property is set to True, the CJC values, in temperature, are interleaved with the channel data; therefore, the returned array will be twice the number of valid samples (`OlBuffer.ValidSamples`). Refer to page 159 for more information on the `ReturnCjcTemperaturesInStream` property.

- **OlBuffer.GetDataAsVoltsByte** – For a specified ChannelListEntry, converts the data from the internal buffer of an OlBuffer object into voltage values, and then copies these voltage values into a user-declared array of bytes. Each temperature value is stored as an Int32, and takes 4 bytes.
  
  To use this method, first declare an array of bytes.

- **OlBuffer.GetDataAsCurrent** – For a specified ChannelListEntry, converts the data from the internal buffer of the OlBuffer object into current values, in Amperes, and copies this data into a user-declared array of 64-bit floating-point (double) values. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.
To use this method, first declare an array of 64-bit floating-point (double) values.

- **OlBuffer.GetDataAsResistance** – For a specified ChannelListEntry, converts the data from the internal buffer of the OlBuffer object into resistance values, in ohms, and copies this data into a user-declared array of 64-bit floating-point (double) values. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

  To use this method, first declare an array of 64-bit floating-point (double) values.

- **OlBuffer.GetDataAsTemperatureByte** – For a specified ChannelListEntry, converts the data from the internal buffer of the OlBuffer object into temperatures based on the specified thermocouple, RTD, or thermistor (described on page 157, page 160, and page 172), and copies this data into a user-declared array of bytes. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

  To use this method, first declare an array of bytes.

  **Note:** If the AnalogInputSubsystem.SupportsTemperatureInDataStream property is True, this method raises an exception if the SupportedChannelInfo.ThermocoupleType is None. If the AnalogInputSubsystem.ReturnCjcTemperaturesInStream property is set to True, the CJC values are interleaved with the channel data; therefore, the returned array will be twice the number of valid samples (OlBuffer.ValidSamples). Refer to page 159 for more information on the ReturnCjcTemperaturesInStream property.

- **OlBuffer.GetDataAsTemperatureDouble** – For a specified ChannelListEntry, converts the data from the internal buffer of the OlBuffer object into temperatures based on the specified thermocouple, RTD, or thermistor (described on page 157, page 160, and page 172), and copies this data into a user-declared array of 64-bit floating-point (double) values. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

  To use this method, first declare an array of 64-bit floating-point (double) values.

  **Note:** If the AnalogInputSubsystem.SupportsTemperatureInDataStream property is True, this method raises an exception if the SupportedChannelInfo.ThermocoupleType is None.

  If the AnalogInputSubsystem.ReturnCjcTemperaturesInStream property is set to True, the CJC values are interleaved with the channel data; therefore, the returned array will be twice the number of valid samples (OlBuffer.ValidSamples). Refer to page 159 for more information on the ReturnCjcTemperaturesInStream property.

- **OlBuffer.GetDataAsRpm** – For a specified ChannelListEntry, converts the tachometer data from the internal buffer of an OlBuffer object into RPM (rotations per minute) values, and then copies these values into a user-declared array of 64-bit floating-point (double) values. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

  To use this method, first declare an array of 64-bit floating-point (double) values.
• **OlBuffer.GetDataAsStrain** – Converts the data from the internal buffer of an OlBuffer object into microstrain values, and then copies these microstrain values into a user-declared array of 64-bit floating-point (double) values. You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer.

To use this method, first declare an array of 64-bit floating-point (double) values.

• **OlBuffer.GetDataAsBridgeBasedSensor** – Converts the data from the internal buffer of an OlBuffer object into the native engineering units of the full-bridge-based sensor, and then copies these values into a user-declared array of 64-bit floating-point (double) values. You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer.

To use this method, first declare an array of 64-bit floating-point (double) values.

• **OlBuffer.GetDataAsNormalizedBridgeOutput** – Converts the data from the internal buffer of an OlBuffer object into the normalized output value of the bridge, in volts, and then copies these values into a user-declared array of 64-bit floating-point (double) values. You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer.

To use this method, first declare an array of 64-bit floating-point (double) values.

• **OlBuffer.Item** property ([]) – Copies the raw count value at the specified index of the buffer specified by the OlBuffer object into a user-declared signed, 32-bit integer variable (int).

When you have finished copying the data from the internal buffer of the OlBuffer object, you can put the OlBuffer object back on the queue for the analog input subsystem using the AnalogInputSubsystem.BufferQueue.QueueBuffer method.

See the example for the event BufferDoneEvent starting on page 259 for an example of using the GetDataAsSensor method to handle input buffers.

**Handling Output Buffers**

For continuous analog output operations, you need to create an array and fill it with data, then copy this data from the array to the internal buffer of the OlBuffer object using one of the following methods:

• **OlBuffer.PutDataAsRaw** – Copies raw counts from a user-specified array into the internal buffer of the OlBuffer object. This is an overloaded method that allows you to copy all the data from the array into the buffer or only the data for a specific ChannelListEntry in the array into the buffer. Note that if the ChannelListEntry occurs more than once in the array, the data for each occurrence of the ChannelListEntry is copied.

If your subsystem supports a resolution of 16-bits or less, declare an array of unsigned, 16-bit integers (ushort) for use with this method.

If your subsystem supports a resolution greater than 16 bits, declare an array of unsigned, 32-bit integers (uint) for use with this method.
• **OlBuffer.PutDataAsVolts** – Copies voltages from a user-specified array into the internal buffer of the OlBuffer object. This is an overloaded method that allows you to copy all the data from the array into the buffer or only the data for a specific ChannelListEntry in the array into the buffer. Note that if the ChannelListEntry occurs more than once in the array, the data for each occurrence of the ChannelListEntry is copied.

Declare an array of 64-bit floating-point values (double) for use with this method.

When you have finished copying the data into the internal buffer of the OlBuffer object, put the OlBuffer object back on the queue for the analog output subsystem using the `AnalogOutputSubsystem.BufferQueue.QueueBuffer` method.

The following example shows how to create an OlBuffer object, fill the internal buffer of this OlBuffer object with 100 samples, and put the OlBuffer object on the analog output subsystem queue:

**Visual C#**
```csharp
// Allocate a buffer of 100 samples
DacBuffer = new OlBuffer(100, aoutSS);
// Create an array of data
for (int i = 0; i < 100; i++)
{
    data[i] = i;
}
// Copy the raw data to the buffer
DacBuffer.PutDataAsRaw(data);
// Queue the buffer for output
aoutSS.BufferQueue.QueueBuffer(DacBuffer);
```

**Visual Basic**
```vbnet
' Allocate a buffer of 100 samples
DacBuffer = New OlBuffer(100, aoutSS)
' Create an array of data
Dim i As Integer
For i = 0 To 99
    data(i) = i
Next i
' Copy the raw data to the buffer
DacBuffer.PutDataAsRaw(data)
' Queue the buffer for output
aoutSS.BufferQueue.QueueBuffer(DacBuffer)
```

**Moving Data from an Inprocess OlBuffer Object**

Some devices allow you to transfer data from the internal buffer of an OlBuffer object while it is being filled. Typically, you would use this method when a continuous analog input operation is running slowly.

To determine if the subsystem supports this capability, use the `AnalogInputSubsystem.SupportsInProcessFlush` property. If this property returns a value of True, your subsystem supports moving data from the internal buffer as it is being filled.
Use the `AnalogInputSubsystem.MoveFromBufferInprocess` method to move data from the internal buffer of an `OlBuffer` object that is in the process of being filled to the internal buffer of a new `OlBuffer` object, which has not been put on the queue.

**Note:** Some devices transfer data to the host in segments instead of one sample at a time. For example, data from the DT3010 device is transferred to the host in 64 byte segments; the number of valid samples is always a multiple of 64 depending on the number of samples transferred to the host when `MoveFromBufferInprocess` was called. It is up to your application to take this into account when flushing an inprocess buffer. Refer to your device documentation for more information.

### Getting Information about a Buffer

The `DT-Open Layers for .NET` Class Library provides the following additional properties for getting information about buffers:

- **`OlBuffer.BufferSizeInBytes`** – Returns the size, in bytes, of the internal data buffer that is encapsulated by the `OlBuffer` object.

- **`OlBuffer.BufferSizeInSamples`** – Returns the size, in samples, of the internal data buffer that is encapsulated by the `OlBuffer` object.

- **`OlBuffer.ChannelListOffset`** – Returns the index into the ChannelList that corresponds to the first sample in the internal buffer of the `OlBuffer` object.

- **`OlBuffer.Encoding`** – Returns the data encoding for the raw data (binary or two’s complement) in the internal buffer of the `OlBuffer` object.

- **`OlBuffer.RawDataFormat`** – Returns the format of the raw data (Int16, Uint16, Int32, Float 32-bit float, or Double 64-bit float) in the internal buffer of the `OlBuffer` object.

- **`OlBuffer.Resolution`** – Returns the resolution of the subsystem that is associated with the `OlBuffer` object.

- **`OlBuffer.SampleSizeInBytes`** – Returns the size of a sample, in bytes. Typically, each sample requires 2 bytes.

- **`OlBuffer.State`** property – Returns the state of the `OlBuffer` object. Valid states are as follows:
  - **Idle** – The `OlBuffer` object has been created, but has not been queued to a subsystem.
  - **Queued** – The `OlBuffer` object has been queued to a subsystem with `OlBuffer.QueueBuffer`.
  - **InProcess** – The `OlBuffer` object has been sent to the device driver for processing. A maximum of eight `OlBuffer` objects can be inprocess at one time.
  - **Completed** – For an input operation, the internal buffer of the `OlBuffer` object has been filled, and the `OlBuffer` object has not been put back on queue for the subsystem. For an output operation, all the data in the internal buffer of the `OlBuffer` object has been output, and the `OlBuffer` object has not been put back on the queue for the subsystem.
  - **Released** – The internal data buffer of the `OlBuffer` object has been deallocated by calling `OlBuffer.Dispose`. 
• **OlBuffer.ValidSamples** – Returns the number of valid samples in the internal buffer of the OlBuffer object.

For analog input operations, the `ValidSamples` property is set to the number of samples in the completed buffer under normal circumstances. However, in some cases, like if `Abort` is called in the middle of an operation, `ValidSamples` reflects the number of samples in the buffer when `Abort` was called. In addition, if `Abort` or `Stop` is called, any OlBuffer object whose state is Inprocess will have a `ValidSamples` of 0.

**Note:** If the `AnalogInputSubsystem.ReturnCjcTemperaturesInStream` property is set to True, the CJC values will be interleaved with the channel data; therefore, the returned array will be twice the number of valid samples (OlBuffer.ValidSamples). Refer to page 159 for more information on the `ReturnCjcTemperaturesInStream` property.

For analog output operations, `ValidSamples` is always equal to the maximum number of samples that the buffer was allocated to hold.

• **OlBuffer.VoltageRange** – Returns the upper limit and lower limit of the voltage range for the associated subsystem.

### Cleaning up Buffers

When you are finished performing continuous analog I/O operations, use can use one of the following methods to clean up the OlBuffer objects:

• **BufferQueue.DequeueBuffer** – Removes and returns the OlBuffer object at the front of the queue.

• **BufferQueue.FreeAllQueuedBuffers** – Removes all OlBuffer objects from the queue and deallocates the internal data buffers that are encapsulated by them.

### Setting Triggered Scan Mode

**Note:** Single-value operations do not support triggered scan mode.

On some devices, the analog input subsystem supports triggered scan mode. In triggered scan mode, the device scans the channel list a specified number of times when it detects the specified retrigger source, acquiring the data for each channel in the channel list. The conversion rate of each channel in the scan is determined by the frequency of the A/D sample clock; refer to page 212 for more information on clock sources. The conversion rate of each scan is determined by the period between retriggers.

To determine if the subsystem supports triggered scan mode, use the `AnalogInputSubsystem.SupportsTriggeredScan` property. If this property returns a value of True, triggered scan mode is supported.

To enable (or disable) triggered scan mode, use the `TriggeredScan.Enabled` property.
To determine the maximum number of times that the device can scan the channel list per retrigger, use the `TriggeredScan.MaxMultiScanCount` property.

Use the `TriggeredScan.MultiScanCount` property to set or get the number of times to scan the channel list per retrigger.

Use the `TriggeredScan.RetriggerSource` property to specify the retrigger source; the retrigger source can be any of the supported trigger sources. Refer to page 213 for more information on the supported trigger sources. The following subsections describe considerations when using a software or external retrigger source.

**Using a Software Retrigger Source**

If you are using a software retrigger source, specify the period between retriggers using the `TriggeredScan.RetriggerFrequency` property.

You can determine the maximum retrigger frequency supported by the subsystem using the `TriggeredScan.MaxRetriggerFreq` property. You can determine the minimum retrigger frequency supported by the subsystem using the `TriggeredScan.MinRetriggerFreq` property.

When it detects an initial trigger (pre-trigger source or post-trigger source), the device scans the channel list a specified number of times (determined by the `TriggeredScan.MultiscanCount` property), then stops. When the software retrigger occurs, determined by the frequency of the internal retrigger clock, the process repeats.

We recommend that you set the retrigger frequency as follows:

\[
\text{Min. Retrigger} = \frac{\# \text{ of CGL entries} \times \# \text{ of CGLs per trigger} + 2 \mu s}{\text{A/D sample clock frequency}}
\]

\[
\text{Max. Retrigger} = \frac{1}{\text{Frequency Min. Retrigger Period}}
\]

For example, if you have 512 ChannelListEntry objects in the ChannelList object, are scanning the channel list 256 times every trigger or retrigger, and are using an A/D sample clock with a frequency of 1 MHz, set the maximum retrigger frequency to 7.62 Hz, since

\[
7.62 \text{ Hz} = \frac{1}{\frac{(512 \times 256) + 2 \mu s}{1 \text{ MHz}}}
\]

**Using an External Retrigger Source**

If you are using an external retrigger source, the period between retriggers cannot be accurately controlled. The device ignores external triggers that occur while it is acquiring data. Only retrigger events that occur when the device is waiting for a trigger are detected and acted on. Some devices may generate the event DriverRunTimeErrorEvent. Refer to page 266 for more information on this event.

Refer to page 213 and to your device/device driver documentation for supported external retrigger sources.
Performing Digital I/O Operations

Using the DT-Open Layers for .NET Class Library, you can perform the following types of digital input operations:

- Single-value digital input, described below
- Single-value digital output, described on page 230
- Continuous digital input (interrupt-on-change), described on page 230

Single-Value Digital Input Operations

In a single-value digital input operation, a single data value is read from a single digital input port. The operation occurs immediately.

To determine if the subsystem supports single-value operations, use the DigitalInputSubsystem.SupportsSingleValue property. If this property returns a value of True, the subsystem supports single-value operations.

Once you have a DigitalInputSubsystem object, as described on page 146, set up the DigitalInputSubsystem object for a single value operation as follows:

2. (Optional) Set the resolution of the subsystem using the DigitalInputSubsystem.Resolution property. Refer to page 231 for more information on resolution.

Then, to acquire a single value from the digital input port, use the DigitalInputSubsystem.GetSingleValue method. You specify the digital input port to read and a gain of 1.

Single-value operations stop automatically when finished; you cannot stop a single-value operation in software.

Note: If your device supports it, you can read a digital input port as part of the analog input stream. Ensure that you set up and configure the digital input subsystem, as described in this section, before starting the analog input operation. Refer to page 204 for more information on specifying a ChannelList object for an analog input subsystem.

Refer to the example program ReadSingleValue to see how to perform a single-value digital input operation.
Single-Value Digital Output Operations

In a single-value digital output operation, a single data value is output from a single digital output port. The operation occurs immediately.

To determine if the subsystem supports single-value operations, use the DigitalOutputSubsystem.SupportsSingleValue property. If this property returns a value of True, the subsystem supports single-value operations.

Once you have a DigitalInputSubsystem object, as described on page 146, set up the DigitalInputSubsystem object for a single value operation as follows:

2. (Optional) Set the resolution of the subsystem using the DigitalOutputSubsystem.Resolution property. Refer to page 231 for more information on resolution.

Then, to output a single value from the digital output port, use the DigitalOutputSubsystem.SetSingleValue method. You specify the digital output port to update and a gain of 1.

Single-value operations stop automatically when finished; you cannot stop a single-value operation in software.

Note: If your device supports it, you can update a digital output port as part of the analog output stream. Ensure that you set up and configure the digital output subsystem, as described in this section, before starting the analog output operation. Refer to page 204 for more information on specifying a ChannelList object for an analog output subsystem.

Refer to the example program WriteSingleValue to see how to perform a single-value digital output operation.

Continuous, Interrupt-On-Change Operations

Use continuous digital input operation when you want to continuously monitor the state of the digital input lines, generating an interrupt when a digital input line changes state.

To determine if the digital input subsystem supports continuous operations, use the DigitalInputSubsystem.SupportsContinuous property. If this property returns a value of True, continuous mode is supported.

To determine if the digital input subsystem supports interrupt-on-change operations, use the DigitalInputSubsystem.SupportsInterruptOnChange property. If this property returns a value of True, interrupt-on-change operations are supported.
Once you have an DigitalInputSubsystem object, as described on page 146, set up the DigitalInputSubsystem object for a continuous operation as follows:

2. (Optional) Set the resolution of the subsystem using the DigitalInputSubsystem.Resolution property. Refer to page 231 for more information on resolution.

3. Select the digital input lines that you want to monitor for change of state using the WriteInterruptOnChangeMask method. (Note that you can read the current mask setting by using the DigitalInputSubsystem.ReadInterruptOnChangeMask method.)

Once the subsystem is configured, call the DigitalInputSubsystem.Start method to start the interrupt-on-change operation.

An InterruptOnChangeEvent event is raised whenever one of the selected digital input lines (specified by the WriteInterruptOnChangeMask method) changes state. Use the InterruptOnChangeHandler, described on page 268, to deal with InterruptOnChangeEvent events.

To stop a continuous digital input operation, use one of the following methods:

- DigitalInputSubsystem.Stop – Stops the digital input operation.
- DigitalInputSubsystem.Abort – For this subsystem type, behaves like Stop.
- Reset – Stops the operation immediately, and reinitializes the subsystem to the default configuration.

Refer to the example program InterruptOnChange to see how to perform a continuous, interrupt-on-change operation on a digital input port.

**Setting the Resolution**

To determine if the subsystem supports software-programmable resolution, use the SupportsSoftwareResolution property of the appropriate subsystem. If this property returns a value of True, the subsystem supports software-programmable resolution.

To determine the number of resolution settings supported by the subsystem, use the NumberOfResolutions property of the appropriate subsystem. To list all the resolution settings supported by the subsystem, use the SupportedResolutions property of the appropriate subsystem.

Use the Resolution property of the appropriate subsystem to set and/or return the number of bits of resolution for the subsystem. Typically, you can set this property for digital I/O operations only.
Performing Counter/Timer Operations

The counter/timer subsystem supports general-purpose user counter/timers and measure counters. This section describes the operation of general-purpose counter/timers. Refer to page 249 for information on measure counters.

Each user counter/timer channel accepts a clock input signal and gate input signal and outputs a clock output signal (also called a pulse output signal), as shown in Figure 5.

Each counter/timer channel corresponds to a counter/timer (C/T) subsystem. To specify the counter to use in software, specify the appropriate C/T subsystem. For example, counter 0 corresponds to C/T subsystem element 0; counter 3 corresponds to C/T subsystem element 3.

Using the DT-Open Layers for .NET Class Library, you can perform the following types of counter/timer operations.

- Event counting, described on page 232
- Up/down counting, described on page 234
- Edge-to-edge measurement, described on page 235
- Continuous edge-to-edge measurement, described on page 237
- Rate generation (continuous pulse output), described on page 239
- One-shot, described on page 241
- Repetitive one-shot, described on page 242

The following subsections describe these counter/timer operations in more detail.

Event Counting

Use event counting mode to count events from the counter’s associated clock input source.

To determine if the subsystem supports event counting, use the `CounterTimerSubsystem.SupportsCount` property. If this property returns a value of True, event counting mode is supported.
Once you have a CounterTimerSubsystem object, as described on page 146, set up the CounterTimerSubsystem object for a event counting operation as follows:

1. Set the `CounterTimerSubsystem.DataFlow` property to Continuous.
2. Set the `CounterTimerSubsystem.CounterMode` property to a value of Count.
3. Specify the C/T clock source for the operation. In event counting mode, an external C/T clock source is more useful than the internal C/T clock source. Refer to page 244 for more information on specifying a clock source.
4. (Optional) Set the cascade mode of the counter/timer subsystem to either Cascade for cascaded counter/timers or Single for non-cascaded counter/timers using the `CounterTimerSubsystem.CascadeMode`. Refer to page 245 for more information.
5. Specify the gate type that enables the operation; refer to page 245 for more information on specifying the gate type.
6. Configure the subsystem using the `CounterTimerSubsystem.Config` method.

Start an event counting operation using the `CounterTimerSubsystem.Start` method. To read the current number of events counted, use the `CounterTimerSubsystem.ReadCount` method.

To stop an event counting operation, call the `CounterTimerSubsystem.Stop` or `CounterTimerSubsystem.Abort` method. For this subsystem type, `Stop` and `Abort` behave identically.

Figure 6 shows an example of an event counting operation. In this example the gate type is low level.

![Figure 6: Example of Event Counting](image)

Refer to the example program EventCounting to see how to perform an event counting operation.
Up/Down Counting

Use up/down counting mode to increment or decrement the number of rising edges that occur on the counter’s associated clock input, depending on the level of the counter’s associated gate signal. If the gate signal is high, the C/T increments; if the gate signal is low, the C/T decrements.

To determine if the subsystem supports up/down counting, use the `CounterTimerSubsystem.SupportsUpDown` property. If this property returns a value of True, up/down counting mode is supported.

Once you have a CounterTimerSubsystem object, as described on page 146, set up the CounterTimerSubsystem object for an up/down counting operation as follows:

1. Set the `CounterTimerSubsystem.DataFlow` property to Continuous.
2. Set the `CounterTimerSubsystem.CounterMode` property to a value of UpDown.
3. Specify the C/T clock source for the operation as External; see page 244 for more information on C/T clock sources.

**Note:** For up/down counting operations, you do not specify the gate type in software.

4. Start the up/down counting operation using the `CounterTimerSubsystem.Start` method.
5. Read the number of rising edges counted using the `CounterTimerSubsystem.ReadCount` method.

To stop an up/down counting operation, call the `CounterTimerSubsystem.Stop` or `CounterTimerSubsystem.Abort` method. For this subsystem type, Stop and Abort behave identically.

**Figure 7** shows an example of an up/down counting operation. The counter increments when the gate signal is high and decrements when the gate signal is low.

![Figure 7: Example of Up/Down Counting](image-url)
Refer to the example program EventCounting to see how to perform an up/down counting operation.

**Edge-to-Edge Measurement**

Use edge-to-edge measurement to measure the time interval between a specified start edge and a specified stop edge. The start edge and the stop edge can occur on the rising edge of the counter’s associated gate input, the falling edge of the counter’s associated gate input, the rising edge of the counter’s associated clock input, or the falling edge of the counter’s associated clock input. When the start edge is detected, the counter starts incrementing, and continues incrementing until the stop edge is detected.

You can use edge-to-edge measurement to measure the following:

- **Pulse width of a signal pulse** (the amount of time that a signal pulse is in a high or a low state, or the amount of time between a rising edge and a falling edge or between a falling edge and a rising edge). You can calculate the pulse width as follows:
  - $\text{Pulse width} = \frac{\text{Number of counts}}{\text{Internal CT Clock Freq}}$

- **Period of a signal pulse** (the time between two occurrences of the same edge – rising edge to rising edge or falling edge to falling edge). You can calculate the period as follows:
  - $\text{Period} = \frac{1}{\text{Frequency}}$
  - $\text{Period} = \frac{\text{Number of counts}}{\text{Internal CT Clock Freq}}$

- **Frequency of a signal pulse** (the number of periods per second). You can calculate the frequency as follows:
  - $\text{Frequency} = \frac{\text{Internal CT Clock Freq}}{\text{Number of Counts}}$

To determine if the subsystem supports edge-to-edge measurements, use the `CounterTimerSubsystem.SupportsMeasure` property. If this property returns a value of True, edge-to-edge measurement mode is supported.

To determine which edges can be selected in an edge-to-edge measurement operation, use the following properties:

- `CounterTimerSubsystem.SupportsGateRising` – Returns a value of True if the rising edge of the gate signal can be used in an edge-to-edge measurement operation.

- `CounterTimerSubsystem.SupportsGateFalling` – Returns a value of True if the falling edge of the gate signal can be used in an edge-to-edge measurement operation.

- `CounterTimerSubsystem.SupportsClockRising` – Returns a value of True if the rising edge of the clock signal can be used in an edge-to-edge measurement operation.

- `CounterTimerSubsystem.SupportsClockFalling` – Returns a value of True if the falling edge of the clock signal can be used in an edge-to-edge measurement operation.

You can also use the `CounterTimerSubsystem.SupportedEdgeTypes` property. This property returns an array of supported edge types.
Once you have a CounterTimerSubsystem object, as described on page 146, set up the CounterTimerSubsystem object for an edge-to-edge measurement operation as follows:

1. Set the CounterTimerSubsystem.DataFlow property to Continuous.
2. Set the CounterTimerSubsystem.CounterMode property to a value of Measure.
3. Specify the C/T clock source for the operation as internal; refer to page 244 for more information on this clock source.
4. Specify the start edge with the CounterTimerSubsystem.StartEdge property
5. Specify the stop edge with the CounterTimerSubsystem.StopEdge property.
6. Configure the counter(timer) subsystem using the CounterTimerSubsystem.Config method.
7. Start the edge-to-edge measurement operation using the CounterTimerSubsystem.Start method.
8. Use the MeasureDoneHandler delegate to receive the MeasureDoneEventArgs argument and to handle the event MeasureDoneEvent. The MeasureDoneEventArgs class contains the subsystem that raised the event, the time stamp of when the event occurred, and the value of the counter.

To stop an edge-to-edge measurement operation, call the CounterTimerSubsystem.Stop or CounterTimerSubsystem.Abort method. For this subsystem type, Stop and Abort behave identically.

Figure 8 shows an example of an edge-to-edge measurement operation. The start edge is a rising edge on the gate signal; the stop edge is a falling edge on the gate signal.

Refer to the example program MeasureEdgeToEdge to see how to perform an edge-to-edge measurement operation.
Continuous Edge-to-Edge Measurement

In continuous edge-to-edge measurement mode, the counter automatically performs an edge-to-edge measurement operation, where the counter starts incrementing when it detects the specified start edge and stops incrementing when it detects the specified stop edge. When the operation completes, the counter remains idle until it is next read. On the next read, the current value of the counter (from the previous edge-to-edge measurement operation) is returned and the next edge-to-edge measurement operation is started automatically.

Note: If you read the counter before the measurement is complete, 0 is returned.

You can use a continuous edge-to-edge measurement to measure the following:

- Pulse width of a signal pulse (the amount of time that a signal pulse is in a high or a low state, or the amount of time between a rising edge and a falling edge or between a falling edge and a rising edge). You can calculate the pulse width as follows:
  - Pulse width = Number of counts/Internal C/T Clock Freq

- Period of a signal pulse (the time between two occurrences of the same edge - rising edge to rising edge or falling edge to falling edge). You can calculate the period as follows:
  - Period = 1/Frequency
  - Period = Number of counts/Internal C/T Clock Freq

- Frequency of a signal pulse (the number of periods per second). You can calculate the frequency as follows:
  - Frequency = Internal C/T Clock Freq/Number of Counts

To determine if the subsystem supports continuous edge-to-edge measurements, use the `CounterTimerSubsystem.SupportsContinuousMeasure` property. If this property returns a value of True, continuous edge-to-edge measurement mode is supported.

To determine which edges can be selected in a continuous edge-to-edge measurement operation, use the following properties:

- `CounterTimerSubsystem.SupportsGateRising` – Returns a value of True if the rising edge of the gate signal can be used in a continuous edge-to-edge measurement operation.
- `CounterTimerSubsystem.SupportsGateFalling` – Returns a value of True if the falling edge of the gate signal can be used in a continuous edge-to-edge measurement operation.
- `CounterTimerSubsystem.SupportsClockRising` – Returns a value of True if the rising edge of the clock signal can be used in a continuous edge-to-edge measurement operation.
- `CounterTimerSubsystem.SupportsClockFalling` – Returns a value of True if the falling edge of the clock signal can be used in a continuous edge-to-edge measurement operation.

You can also use the `CounterTimerSubsystem.SupportedEdgeTypes` property. This property returns an array of supported edge types.
Once you have a CounterTimerSubsystem object, as described on page 146, set up the CounterTimerSubsystem object for a continuous edge-to-edge measurement operation as follows:

1. Set the `CounterTimerSubsystem.DataFlow` property to Continuous.
2. Set the `CounterTimerSubsystem.CounterMode` property to a value of ContinuousMeasure.
3. Specify the C/T clock source for the operation as Internal; refer to page 244 for more information.
4. Specify the start edge with the `CounterTimerSubsystem.StartEdge` property.
5. Specify the stop edge with the `CounterTimerSubsystem.StopEdge` property.
6. Configure the counter/timer subsystem using the `CounterTimerSubsystem.Config` method. 
   The continuous edge-to-edge measurement operation starts immediately.
7. Read the current value of the counter using the `CounterTimerSubsystem.ReadCount` method.

If your device allows you to stream counter/timer data through the analog input subsystem, you can also add the counter/timer channel to the channel list for an analog input operation. If you read the value of the counter/timer as part of the analog input data stream, you might see results similar to the following:

To stop an edge-to-edge measurement operation, call the `CounterTimerSubsystem.Stop` or `CounterTimerSubsystem.Abort` method. For this subsystem type, `Stop` and `Abort` behave identically.
Rate Generation

Use rate generation mode to generate a continuous pulse output signal from the counter; this mode is sometimes referred to as continuous pulse output or pulse train output. You can use this pulse output signal as an external clock to pace analog input, analog output, or other counter/timer operations.

To determine if the subsystem supports rate generation mode, use the `CounterTimerSubsystem.SupportsRateGenerate` property. If this property returns a value of True, rate generation mode is supported.

Once you have a `CounterTimerSubsystem` object, as described on page 146, set up the `CounterTimerSubsystem` object for a rate generation operation as follows:

1. Set the `CounterTimerSubsystem.DataFlow` property to Continuous.
2. Set the `CounterTimerSubsystem.CounterMode` property to a value of RateGenerator.
3. Specify the C/T clock source for the operation. In rate generation mode, either the internal or external C/T clock input source is appropriate depending on your application. Refer to page 244 for information on specifying the C/T clock source.
4. Specify the frequency of the C/T clock output signal. For an internal C/T source, setting the `Clock.Frequency` property determines the frequency of the output pulse.
   
   For an external C/T clock source, setting the external clock divider using the `Clock.ExtClockDivider` property determines the frequency of the output pulse. The frequency of the clock input source divided by the clock divider determines the frequency of the output pulse. Refer to page 244 for information on specifying the C/T clocks.
5. Specify the gate type that enables the operation; refer to page 245 for more information on specifying the gate type.
6. Specify the polarity of the output pulses (high-to-low transitions or low-to-high transitions) and the duty cycle of the output pulses; refer to page 247 for more information.
7. Configure the counter/timer subsystem using the `CounterTimerSubsystem.Config` method.
8. Start rate generation mode using the `CounterTimerSubsystem.Start` method. The counter outputs a pulse of the specified type and frequency continuously as long as the gate enables the operation. As soon as the gate signal disables the operation, the pulse output operation stops.

To stop rate generation while it is in progress, call the `CounterTimerSubsystem.Stop` or `CounterTimerSubsystem.Abort` method. For this subsystem type, `Stop` and `Abort` behave identically.

Figure 9 shows an example of an enabled rate generation operation using an external C/T clock source with an input frequency of 4 kHz, a clock divider of 4, a low-to-high pulse type, and a duty cycle of 50%. (The gate type does not matter for this example.) A 1 kHz square wave is the generated output.

Refer to the example program PulseOut_RateGeneration to see how to perform a rate generation operation.

### One-Shot

Use one-shot mode to generate a single pulse output signal from the counter when the operation is triggered (determined by the gate input signal). You can use this pulse output signal as an external digital (TTL) trigger to start analog input, analog output, or other operations.

To determine if the subsystem supports one-shot mode, use the `CounterTimerSubsystem.SupportsOneShot` property. If this property returns a value of True, one-shot mode is supported.

Once you have a `CounterTimerSubsystem` object, as described on page 146, set up the `CounterTimerSubsystem` object for a one-shot operation as follows:

1. Set the `CounterTimerSubsystem.DataFlow` property to Continuous.
2. Set the `CounterTimerSubsystem.CounterMode` property to a value of OneShot.
3. Specify the C/T clock source for the operation. Refer to page 244 for more information on specifying the C/T clock source.
4. Specify the gate type that triggers the operation; refer to page 245 for more information.
5. Specify the polarity of the output pulse (high-to-low transition or low-to-high transition); refer to page 247 for more information.

**Note:** In the case of a one-shot operation, the pulse width is automatically set to 100%. The value of the `PulseWidth` property is ignored.
6. Configure the counter/timer subsystem using the `CounterTimerSubsystem.Config` method.

7. Start the one-shot pulse output operation using the `CounterTimerSubsystem.Start` method. When the one-shot operation is triggered (determined by the gate input signal), a single pulse is output; then, the one-shot operation stops. All subsequent clock input signals and gate input signals are ignored.

Figure 12 shows an example of a one-shot operation using an external gate input (rising edge), a clock output frequency of 1 kHz (one pulse every 1 ms), and a low-to-high pulse type.

---

**Figure 12: Example of One-Shot Mode**

Refer to the example program `PulseOut_RateGeneration` to see how to perform a one-shot operation.

**Repetitive One-Shot**

Use repetitive one-shot mode to generate a pulse output signal each time the device detects a trigger (determined by the gate input signal). You can use this mode to clean up a poor clock input signal by changing its pulse width, then outputting it.

To determine if the subsystem supports repetitive one-shot mode, use the `CounterTimerSubsystem.SupportsOneShotRepeat` property. If this property returns a value of True, repetitive one-shot mode is supported.

Once you have a CounterTimerSubsystem object, as described on page 146, set up the CounterTimerSubsystem object for a repetitive one-shot operation as follows:

1. Set the `CounterTimerSubsystem.DataFlow` property to Continuous.
2. Set the `CounterTimerSubsystem.CounterMode` property to a value of OneShotRepeat.
3. Specify the C/T clock source for the operation. In repetitive one-shot mode, the internal C/T clock source is more useful than the external C/T clock source. Refer to page 244 for more information on specifying the C/T clock source.

4. Specify the polarity of the output pulses (high-to-low transitions or low-to-high transitions). Refer to page 247 for more information.

**Note:** In the case of a repetitive one-shot operation, the pulse width is automatically set to 100%. The value of the PulseWidth property is ignored.

5. Specify the gate type that triggers the operation. Refer to page 245 for more information.

6. Configure the counter/timer subsystem using the CounterTimerSubsystem.Config method.

7. Start a repetitive one-shot pulse output operation using the CounterTimerSubsystem.Start method. When the one-shot operation is triggered (determined by the gate input signal), a pulse is output. When the device detects the next trigger, another pulse is output.

To stop a repetitive one-shot operation, call the CounterTimerSubsystem.Stop or CounterTimerSubsystem.Abort method. For this subsystem type, Stop and Abort behave identically.

**Note:** Triggers that occur while the pulse is being output are not detected by the device.

**Figure 13** shows an example of a repetitive one-shot operation using an external gate (rising edge), a clock output frequency of 1 kHz (one pulse every 1 ms), and a low-to-high pulse type.
Refer to the example program PulseOut_RateGeneration to see how to perform a repetitive one-shot operation.

**Setting the C/T Clock**

The DT-Open Layers for .NET Class Library defines the following clock sources for counter/timers:

- Internal C/T clock
- External C/T clock
- Internally cascaded clock

The following subsections describe these clock sources.

**Using an Internal C/T Clock**

The internal C/T clock is the clock source on the device that paces a counter/timer operation for a C/T subsystem.

To determine if the subsystem supports an internal C/T clock, use the `Clock.SupportsInternalClock` property. If this property returns a value of True, an internal C/T clock is supported.

To specify the clock source, use the `Clock.Source` property.

Using the `Clock.Frequency` property, specify the frequency of the clock output signal.

To determine the maximum frequency that the subsystem supports, use the `Clock.MaxFrequency` property. To determine the minimum frequency that the subsystem supports, use the `Clock.MinFrequency` property.

**Using and External C/T Clock**

The external C/T clock is a clock source attached to the counter/timer subsystem that paces counter/timer operations. The external C/T clock is useful when you want to pace at rates not available with the internal clock or if you want to pace at uneven intervals.

To determine if the subsystem supports an external clock, use the `Clock.SupportsExternalClock` property. If this property returns a value of True, an external clock is supported.

Specify the clock source as internal using the `Clock.Source` property. Then, use the `Clock.ExtClockDivider` property to set or get the clock divider used to determine the frequency at which to pace the operation. The clock input source divided by the clock divider determines the frequency of the clock signal.

To determine the maximum external clock divider that the subsystem supports, use the `Clock.MaxExtClockDivider` property. To determine the minimum external clock divider that the subsystem supports, use the `Clock.MinExtClockDivider` property.
Using an Internally Cascaded Clock

You can also internally connect or cascade the clock output signal from one counter/timer to the clock input signal of the next counter/timer in software. In this way, you can create a 32-bit counter out of two 16-bit counters, for example.

To determine if the subsystem supports internal cascading, use the `CounterTimerSubsystem.SupportsCascading` property. If this function returns a value of True, internal cascading is supported.

Set the cascade mode of the subsystem to Cascade or Single (not cascaded) using the `CounterTimerSubsystem.CascadeMode` property.

**Note:** If a counter/timer is cascaded, you specify the clock input and gate input for the first counter in the cascaded pair. For example, if counters 1 and 2 are cascaded, specify the clock input and gate input for counter 1.

Setting the Gate Type

The active edge or level of the gate input to the counter enables or triggers counter/timer operations. The `CounterTimerSubsystem` class defines the following gate input types:

- None (software)
- HighLevel
- LowLevel
- HighEdge
- LowEdge
- Level

To specify the gate type, use the `CounterTimerSubsystem.GateType` property. The following subsections describe these gate types.

Using a None (Software) Gate Type

A gate type of None (software) enables the counter/timer operation immediately when the `CounterTimerSubsystem.GateType` property is set.

To determine if the subsystem supports a software gate, use the `CounterTimerSubsystem.SupportsGateNone` property. If this property returns a value of True, a gate type of None is supported.
**Using a HighLevel Gate Type**

A HighLevel external gate type enables a counter/timer operation when the external gate signal is high, and disables a counter/timer operation when the external gate signal is low. Note that this gate type is used only for the following operations: event counting (see page 232) and rate generation (see page 239).

To determine if the subsystem supports a HighLevel external gate input, use the `CounterTimerSubsystem.SupportsGateHighLevel` property. If this property returns a value of true, a HighLevel gate type is supported.

**Using a LowLevel Gate Type**

A LowLevel external gate type enables a counter/timer operation when the external gate signal is low, and disables the counter/timer operation when the external gate signal is high. Note that this gate type is used only for the following operations: event counting (see page 232) and rate generation (see page 239).

To determine if the subsystem supports a LowLevel external gate input, use the `CounterTimerSubsystem.SupportsGateLowLevel` property. If this property returns a value of true, a LowLevel gate type is supported.

**Using LowEdge Gate Type**

A LowEdge external gate type triggers a counter/timer operation on the transition from the high edge to the low edge (falling edge). Note that this gate type is used only for one-shot and repetitive one-shot mode; refer to page 242 for more information on these modes.

To determine if the subsystem supports a LowEdge external gate input, use the `CounterTimerSubsystem.SupportsGateLowEdge` property. If this property returns a value of true, a LowEdge gate type is supported.

**Using a HighEdge Gate Type**

A HighEdge external gate type triggers a counter/timer operation on the transition from the low edge to the high edge (rising edge). Note that this gate type is used only for one-shot (see page 241) and repetitive one-shot (see page 242) operations.

To determine if the subsystem supports a HighEdge external gate input, use the `CounterTimerSubsystem.SupportsGateHighEdge` property. If this property returns a value of true, a HighEdge gate type is supported.
Using a Level Gate Type

A Level gate type enables a counter/timer operation on the transition from any level on the gate input signal. Note that this gate type is used only for the following operations: event counting (see page 232) and rate generation (see page 239).

To determine if the subsystem supports a Level external gate input, use the CounterTimerSubsystem.SupportsGateLevel property. If this property returns a value of true, a Level gate type is supported.

Setting the Pulse Output Type and Pulse Width

The CounterTimerSubsystem class defines the following pulse output types:

- **High-to-low transitions** – The low portion of the total pulse output period is the active portion of the counter/timer clock output signal.
  
  To determine if the subsystem supports high-to-low transitions on the pulse output signal, use the CounterTimerSubsystem.SupportsHighToLowPulse property. If this property returns a value of True, high-to-low transitions are supported.

- **Low-to-high transitions** – The high portion of the total pulse output period is the active portion of the counter/timer pulse output signal.
  
  To determine if the subsystem supports low-to-high transitions on the pulse output signal, use the CounterTimerSubsystem.SupportsLowToHighPulse property. If this property returns a value of True, low-to-high transitions are supported.

Specify the pulse output type using the CounterTimerSubsystem.PulseType property.

The pulse width (or duty cycle) indicates the percentage of the total pulse output period that is active. A duty cycle of 50, then, indicates that half of the total pulse is low and half of the total pulse output is high.

You can determine whether the pulse width is programmable by using the CounterTimerSubsystem.SupportsVariablePulseWidth property. If this property returns a value of True, the pulse width is programmable.

Specify the pulse width, in percentage, using the CounterTimerSubsystem.PulseWidth property. The default value is 50%.

Note: In the case of a one-shot or repetitive one-shot operation, the pulse width is automatically set to 100%. The value of the PulseWidth property is ignored.

Figure 14 illustrates a low-to-high pulse with a duty cycle of approximately 30%.
Figure 14: Example of a Low-to-High Pulse Output Type
Performing Measure Counter Operations

The counter/timer subsystem supports general-purpose user counter/timers and measure counters. This section describes the operation of measure counters. Refer to page 232 for information on the operation of general-purpose counter/timers.

If your device supports measure counters, set up the CounterTimerSubsystem object for a measure operation as follows:

1. Select the signal/edge that is used to start the measure operation using the CounterTimerSubsystem.StartEdge property.

2. Select the signal/edge that is used to stop the measure operation using the CounterTimerSubsystem.StopEdge property.

The internal counter starts incrementing when it detects the selected start edge of the specified signal and stops incrementing when it detects the selected stop edge of the specified signal.

To determine which signals and edges are supported for the measure counter, use the CounterTimerSubsystem.SupportedEdgeTypes property. This property returns an array of the supported signals/edges.

3. Configure the subsystem using the CounterTimerSubsystem.Config method.

4. Read the value of the measure counter in the analog input data stream by specifying the measure counter in the analog input channel list and reading the values corresponding to that channel from the analog input buffer. Refer to the documentation for your device to determine which channel to specify for the measure counter in the analog input channel list.

When you read the value of the measure counter as part of the analog input data stream, you might see results similar to the following:

</tbody>
</table>
Using the count that is returned from the measure counter, you can determine the following:

- Frequency of a signal pulse (the number of periods per second). You can calculate the frequency as follows:
  
  \[ \text{Frequency} = \frac{\text{Frequency of the internal counter}}{\text{Number of counts} - 1} \]

  For example, if the frequency of the internal counter on the device is 48 MHz and the count is 201, the measured frequency is 240 kHz (48 MHz/200).

- Period of a signal pulse. You can calculate the period as follows:
  
  \[ \text{Period} = \frac{1}{\text{Frequency}} \]
  
  \[ \text{Period} = \frac{\text{Number of counts} - 1}{\text{Frequency of the internal counter}} \]
Performing Tachometer Operations

Some devices allow you to connect a tachometer signal to the device to measure the frequency or period of the tachometer input signal.

Once you have a TachSubsystem object, as described on page 146, set up the TachSubsystem object for a tachometer operation as follows:

1. Set the edge of the tachometer signal that is used for the measurement using the TachSubsystem.EdgeType property.

   In a tachometer operation, the internal counter starts incrementing when it detects the first specified edge of the tachometer input and stops incrementing when it detects the next specified edge of the tachometer input.

   To determine if falling edges of the tachometer signal are supported, use the TachSubsystem.SupportsFallingEdge property. To determine if rising edges of the tachometer signal are supported, use the TachSubsystem.SupportsRisingEdge property.

2. Specify the value of the stale data flag using the TachSubsystem.StaleDataFlagEnabled property. If this flag is True, the most significant bit (MSB) of the value is set to 0 to indicate new data; reading the value before the measurement is complete returns an MSB of 1. If this flag is False, the MSB is always set to 0.

   To determine if the stale data flag is supported, use the TachSubsystem.SupportsStaleDataFlag property.

3. Configure the subsystem using the TachSubsystem.Config method.

4. Read the tachometer measurement from the analog input data stream using the TachSubsystem.Count property or by specifying the tachometer channel in the analog input channel list and reading the values corresponding to that channel from the analog input buffer. Refer to the documentation for your device to determine which channel to specify for the tachometer in the analog input channel list.

5. If desired, convert the returned count to an RPM value by using the OlBuffer.GetDataAsRpm method.

When you read the value of the tachometer input as part of the analog input data stream, you might see results similar to the following:

<table>
<thead>
<tr>
<th>Time</th>
<th>A/D Value</th>
<th>Tachometer Input Value</th>
<th>Status of Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>5002</td>

</tr>
<tr>

</tbody>
</table>
Using the count that is returned from the tachometer input, you can determine the following:

- Frequency of a signal pulse (the number of periods per second). You can calculate the frequency as follows:
  - Frequency = Frequency of the internal counter / (Number of counts – 1)

  For example, if the frequency of the internal counter on the device is 12 MHz and the count is 21, the measured frequency is 600 kHz (12 MHz / 20).

- Period of a signal pulse. You can calculate the period as follows:
  - Period = 1 / Frequency
  - Period = (Number of counts – 1) / Frequency of the internal counter

Performing Quadrature Decoder Operations

Some devices support quadrature decoder operations. A quadrature decoder accepts signals (A, B, and Index) from a quadrature encoder as inputs and converts these signals into a clock output signal whose pulses are counted by the decoder.

To determine whether your subsystem supports quadrature decoder functionality, use the `QuadratureDecoder.SupportsQuadratureDecoder` property. If this property returns a value of True, your subsystem supports quadrature decoder functionality.

Once you have a `QuadratureDecoderSubsystem` object, as described on page 146, set up the `QuadratureDecoderSubsystem` object for a quadrature decoder operation as follows:

1. Set the `QuadratureDecoderSubsystem.DataFlow` property to Continuous.
2. Set the clock source to External with `QuadratureDecoder.Clock.Source`. Refer to page 254 for more information.
3. Set the pre-scale value used to divide the base clock frequency using the `QuadratureDecoderSubsystem.ClockPreScale` property. Refer to page 254 or more information.
4. Set the value of the `QuadratureDecoderSubsystem.X4Scaling` property to True if you want to use X4 mode, or False if you want to use X1 mode. Refer to page 254 for more information.
5. Set the value of the `QuadratureDecoderSubsystem.IndexMode` property to Disabled if you do not want to use the Index input signal, Low if the Index input signal is low, or High if the Index input signal is high. Refer to page 254 for more information.
6. Configure the subsystem using the `QuadratureDecoderSubsystem.Config` method.
7. Start the operation using the `QuadratureDecoderSubsystem.Start` method.
8. Read the current value of the quadrature decoder subsystem using the `QuadratureDecoderSubsystem.ReadCount` method.

The value of the quadrature decoder determines the relative or absolute position and/or rotational speed. For example, in an X/Y positioning application, you could use one quadrature decoder to determine the position on the X-plane, and another quadrature decoder to determine the position on the Y-plane.

To determine the rotation of a quadrature encoder, use the following formula:

\[
Rotation \ degrees = \frac{Count \times 360 \ degrees}{4 \times N}
\]

where \( N \) is the number of pulses generated by the quadrature encoder per rotation. For example, if every rotation of the quadrature encoder generated 10 pulses, and the value read from the quadrature decoder is 20, the rotation of the quadrature encoder is 180 degrees (20/40 x 360 degrees).

Refer to the example program `ReadCounts` to see how to perform a quadrature decoder operation.
Setting up the Clock

For quadrature decoder operations, the onboard base clock of the hardware device is used to sample the A and B inputs. From a software perspective, the software considers the A and B inputs as external clock sources, therefore, you must specify the clock source as External using the `Clock.Source` property.

You can filter the sampling frequency of the onboard base clock by using the `QuadratureDecoderSubsystem.ClockPreScale` property to divide down the base frequency. Values for this property range from 0 and 255, where 0 corresponds to an actual pre-scale value of 1, and 255 corresponds to an actual prescale value of 256. For example, if you are using a device with a base clock of 36 MHz and specify a pre-scale value of 0, the resulting sampling frequency is 36 MHz (36 MHz/1). Similarly, if you specify a pre-scale value of 255 when using a device with a 48 MHz base clock, the resulting sampling frequency is 18.75 kHz (48 MHz/256).

The filter samples the incoming A and B signals twice, and when it samples a change in the state of any of these signals and the change is present for two samples, the change on the inputs is valid. A minimum of 4 clock pulses is needed to sample each edge of the A and B inputs in one cycle (for a total of 16 clock pulses). In addition, the minimum time between one edge and the next edge is 112 ns. So, if you are using a 36 MHz sample frequency, the A and B inputs can have a maximum frequency of 2.23 MHz, or a period of 448 ns.

In general, if the `QuadratureDecoder.ClockPreScale` value is set too low, the system is more susceptible to noise on the inputs. If the `QuadratureDecoder.ClockPreScale` value is set too high, counts may be missed.

Setting the X4Scaling Mode

You can control whether the quadrature decoder operates in X1 or X4 mode (if it is supported by the encoder) by using the `QuadratureDecoderSubsystem.X4Scaling` property.

Setting the `QuadratureDecoderSubsystem.X4Scaling` property to False selects X1 mode; in X1 mode, the decoder generates one clock pulse for every complete cycle of the A and B inputs. Setting the `QuadratureDecoderSubsystem.X4Scaling` property to True selects X4 mode; in X4 mode, the decoder generates one clock pulse for each edge of the A and B signals – four edges for each cycle of the A and B inputs.

Setting the Index

Using the `QuadratureDecoderSubsystem.IndexMode` property, you can specify how the Index input signal affects the operation of the counter. If you set this property to Disabled, then the Index input signal has no effect. If you set this property to Low, then the quadrature decoder resets its value to 0 whenever it detects a low edge (falling edge) on the Index input signal. If you set this property to High, then the quadrature decoder resets its value to 0 whenever it detects the high edge (rising edge) on the Index input signal.

**Note:** You must set the `IndexMode` property to Disabled if you set the `X4Scaling` property to True.
Starting Subsystems Simultaneously

If supported, you can set up subsystems to start simultaneously. Note that you cannot perform simultaneous startup on subsystems configured for single-value operations unless you are using a simultaneous sampling module.

To determine if a subsystem supports simultaneous start, use the `SupportsSimultaneousStart` property inherited from the `SubsystemBase` class. If this property returns a value of True, the subsystem can be simultaneously started.

You can synchronize the triggers of subsystems by specifying the same trigger source for each of the subsystems that you want to start simultaneously; ensure that the triggers are wired appropriately to the device.

Use the `SimultaneousStart.AddSubsystem` method to add the subsystems that you want to start simultaneously to the start list. If, later, you want to remove a subsystem from the start list, use the `SimultaneousStart.RemoveSubsystem` method.

To return an array of subsystems that were added to the simultaneous start list, use the `SimultaneousStart.GetSubsystemList` method.

Pre-start the subsystems using the `SimultaneousStart.PreStart` method. Pre-starting a subsystem ensures a minimal delay once the subsystems are started. Once you call the `SimultaneousStart.PreStart` method, do not alter the settings of the subsystems on the simultaneous start list.

Start the subsystems using the `SimultaneousStart.Start` method. When started, both subsystems are triggered simultaneously.

When you are finished with the operations, call the `SimultaneousStart.Clear` method to remove the subsystems from the simultaneous start list.
Auto-Calibrating a Subsystem

Some devices provide a self-calibrating feature, where a specified subsystem performs an auto-zero function. To determine if the specified subsystem supports this capability, use the AnalogInputSubsystem.SupportsAutoCalibrate property. If this property returns a value of True, the subsystem can be calibrated through software.

To calibrate the subsystem in software, call the AutoCalibrate method. Ensure that the subsystem is not running when you call this method, or an error is returned.
**Handling Events**

DT-Open Layers devices notify your application of buffer movement and other system activities by raising events.

Delegates, which behave like function pointers, are provided to handle these events. Each delegate has a specific signature and holds a reference to a method that matches its signature. When an event occurs, the appropriate method (with the matching signature) is called.

The following example shows the declaration for the `BufferDoneHandler` delegate provided by the DT-Open Layers for .NET Class Library:

[C#]
```
// BufferDoneHandler is the delegate for the BufferDoneEvent event.
// BufferDoneEventArgs is the class that holds event data for BufferDoneEvent.
// It derives from the base class for event data, GeneralEventArgs.
public delegate void BufferDoneHandler(object sender, BufferDoneEventArgs eventArgs);
```

[Visual Basic]
```
' BufferDoneHandler is the delegate for the BufferDoneEvent event.
' BufferDoneEventArgs is the class that holds event data for BufferDoneEvent.
' It derives from the base class for event data, GeneralEventArgs.
Public Delegate Sub BufferDoneHandler(sender As Object, eventArgs As BufferDoneEventArgs)
```

As you can see, the syntax of the delegate is similar to that of a method declaration; however, the delegate keyword informs the compiler that `BufferDoneHandler` is a delegate type. By convention, event delegates in the .NET Framework have two parameters, the source that raised the event and the data for the event.

To handle events, you must define a method that matches the delegate; this is the event handling method that is called when the appropriate event is raised. In the following example, the event handling method called `MyBufferDone` matches the signature of the `BufferDoneHandler` delegate and is called when the event `BufferDoneEvent` is raised:

**Visual C#**
```
// MyBufferDone has the same signature as BufferDoneHandler.
public void MyBufferDone (object sender, BufferDoneEventArgs eventArgs);
{
    //Add you own code here.
}
```
Visual Basic
' MyBufferDone has the same signature as BufferDoneHandler.
    Public Sub MyBufferDone(sender As Object,
            eventArgs As BufferDoneEventArgs)
' Add your own code here
    End Sub

Note: To ensure that events are handled in the main application, use the InvokeRequired method. Refer to your .NET documentation for more information on this method.

Lastly, you must associate the event and event handling method with the appropriate subsystem. The following example shows how to associate the event BufferDoneEvent and the MyBufferDoneHandler event handler to the analog input subsystem called ainSS:

Visual C#
// Associate the event BufferDoneEvent and the event handling method
// MyBufferDone with the analog input subsystem ainSS.
    ainSS.BufferDoneEvent += new BufferDoneHandler (MyBufferDoneHandler);

Note: In C#, when you want to disable receiving events, use the -= operator instead of the += operator. See your .NET documentation for more information about events and delegates.

Visual Basic
' Associate the event BufferDoneEvent and the event handling method
' MyBufferDone with the analog input subsystem ainSS.
    AddHandler ainSS.BufferDoneEvent, Address of MyBufferDoneHandler

Note: In Visual Basic, when you want to disable receiving events, use the RemoveHandler statement instead of the AddHandler statement. See your .NET documentation for more information about events and delegates.

The following subsections describe the events and delegates that are provided in the DT-Open Layers for .NET Class Library. Refer to the examples provided with this software package to see how to incorporate event handling code into your program.
BufferDoneEvent

For input operations, the event BufferDoneEvent is raised when the internal data buffer of the OlBuffer object has been filled with post-trigger data. For output operations, this event is raised when all the data in the internal data buffer of the OlBuffer object has been output.

If you stop an analog I/O operation, the event BufferDoneEvent is generated for the current OlBuffer object and for up to eight inprocess OlBuffer objects before a QueueStoppedEvent event occurs.

Use the BufferDoneHandler delegate with BufferDoneEvent. When BufferDoneEvent is raised, the subsystem that raised the event, the time stamp of when the event occurred, and the completed OlBuffer object are passed in the BufferDoneEventArgs argument of the user-defined method that matches the signature of the BufferDoneHandler delegate.

You can add your own code to the event handling method to manage the data in the buffer or perform other operations as required by your application. Refer to page 221 for more information on handling input buffers; refer to page 224 for more information on handling output buffers.

Note: If your program is running under a heavy CPU load, and if the AnalogInputSubsystem.SynchronousBufferDone property is set to False (the default condition), .NET may call your BufferDoneEvent delegates out of order under some circumstances. To avoid this problem, it is recommended that you set the AnalogInputSubsystem.SynchronousBufferDone property to True, so that all BufferDoneEvent events are executed synchronously in a single worker thread instead of asynchronously using a separate thread for each event.

The following is an example of an event handling routine called HandleBufferDone that handles the event BufferDoneEvent. This event handler converts the data from the internal buffer of the OlBuffer object into sensor values and copies the data into a user-dimensioned array called buf. The first 10 samples are printed to the form, and the OlBuffer object is put back on the queue for the subsystem:

Visual C#
public void HandleBufferDone (object sender, BufferDoneEventArgs bufferDoneData) {
    if (this.InvokeRequired) {
        this.Invoke( new BufferDoneHandler (HandleBufferDone),
                    new object[] {sender, bufferDoneData });
    }
}
else
{
    // Get the data as sensor values
    double[] buf = olBuffer.GetDataAsSensor();
    // requeue the completed buffer
    ainSS.BufferQueue.QueueBuffer(olBuffer);
    // Output the first 10 samples to the user form
    for (int i = 0; i < 10; ++i)
    {
        OlBufferDataTable.Rows[i][0] = buf[i];
    }
}

Visual Basic
Public Sub HandleBufferDone(ByVal sender As Object,
                           ByVal bufferDoneData As BufferDoneEventArgs)
    If Me.InvokeRequired Then
        Me.Invoke(New BufferDoneHandler(
            AddressOf HandleBufferDone), New Object()
            {sender, bufferDoneData})
    Else
        ' Get the data as sensor values
        Dim buf As Double() = olBuffer.GetDataAsSensor()
        ' requeue the completed buffer
        ainSS.BufferQueue.QueueBuffer(olBuffer)
    End If
    ' Output the first 10 samples to the user form
    Dim i As Integer
    While i < 10
        OlBufferDataTable.Rows(i)(0) = buf(i)
        i += 1
    End While
End Sub 'HandleBufferDone
PreTriggerBufferDoneEvent

The event PreTriggerBufferDone is raised when the internal buffer of the OlBuffer object is filled with pre-trigger data (for an input operation only). Refer to page 218 for more information about buffers.

Use the PreTriggerBufferDoneHandler delegate with PreTriggerBufferDoneEvent. When PreTriggerBufferDoneEvent is raised, the subsystem that raised the event, the time stamp of when the event occurred, and the completed OlBuffer object are passed in the BufferDoneEventArgs argument of the user-defined method that matches the signature of the PreTriggerBufferDoneHandler delegate.

You can add your own code to the event handling method to manage the data in the buffer or perform other operations as required by your application. Refer to page 221 for more information on handling input buffers.

The following is an example of an event handling routine called HandlePreTriggerBufferDone that handles the event PreTriggerBufferDoneEvent. This event handler converts the data from the internal buffer of the OlBuffer object into voltage values and copies the data into a user-dimensioned array called buf. The first 10 samples are printed to the form, and the OlBuffer object is put back on the queue for the subsystem:

Visual C#

public void HandlePreTriggerBufferDone (object sender, BufferDoneEventArgs bufferDoneData)
{
    if (this.InvokeRequired)
    {
        this.Invoke( new PreTriggerBufferDoneHandler( 
            HandlePreTriggerBufferDone), new object[] { sender, 
            bufferDoneData});
    } else
    {
        // Get the data as voltages
        double[] buf = olBuffer.GetDataAsVolts();

        // requeue the completed buffer
        ainSS.BufferQueue.QueueBuffer (olBuffer);

        // Output the first 10 samples to the user form
        for (int i=0; i<10; ++i)
        {
            OlBufferDataTable.Rows[i][0] = buf[i];
        }
    }
}
Visual Basic

Public Sub HandlePreTriggerBufferDone(ByVal sender As Object,
ByVal bufferDoneData As BufferDoneEventArgs)
If Me.InvokeRequired Then
    Me.Invoke(New PreTriggerBufferDoneHandler(
        AddressOf HandlePreTriggerBufferDone),
        New Object() {sender, bufferDoneData})
Else
    ' Get the data as voltages
    Dim buf As Double() = olBuffer.GetDataAsVolts()
    ' requeue the completed buffer
    ainSS.BufferQueue.QueueBuffer(olBuffer)
End If
' Output the first 10 samples to the user form
Dim i As Integer
While i < 10
    OlBufferDataTable.Rows(i)(0) = buf(i)
    i += 1
End While
End Sub 'HandleBufferDone

QueueStoppedEvent

A QueueStoppedEvent is raised when Stop or Abort is called for a continuous analog input or analog output operation.

---

**Note:** The event BufferDoneEvent is generated for the current OlBuffer object and for up to eight inprocess OlBuffer objects before a QueueStoppedEvent event occurs.

---

Use the QueueStoppedHandler delegate with QueueStoppedEvent. When QueueStoppedEvent is raised, the subsystem that raised the event and the time stamp of when the event occurred are passed in the GeneralEventArgs argument of the user-defined method that matches the signature of the QueueStoppedHandler delegate.

The following is an example of an event handling routine called HandleQueueStopped that handles the event QueueStoppedEvent. This event handler displays a message on the form that indicates which subsystem raised the QueueStoppedEvent and at what time the event occurred:
Visual C#

```csharp
public void HandleQueueStopped (object sender,
    GeneralEventArgs eventData)
{
    if (this.InvokeRequired)
    {
        this.Invoke(new QueueStoppedHandler(HandleQueueStopped),
            new object[] { sender, eventData });
    }
    else
    {
        string msg = String.Format ("Queue Stopped received on
            subsystem {0} element {1} at time {2}",
            eventData.Subsystem, eventData.Subsystem.Element,
            eventData.DateTime.ToString("T"));

        statusBarPanel.Text = msg;
    }
}
```

Visual Basic

```vbnet
Public Sub HandleQueueStopped(ByVal sender As Object,
    ByVal eventData As GeneralEventArgs)
    If Me.InvokeRequired Then
        Me.Invoke(New QueueStoppedHandler(
            AddressOf HandleQueueStopped),
            New Object() {sender, eventData})
    Else
        Dim msg As String = String.Format ("Queue Stopped received on subsystem {0} element {1} at time {2}",
            eventData.Subsystem, eventData.Subsystem.Element,
            eventData.DateTime.ToString("T"))
        statusBarPanel.Text = msg
    End If
End Sub 'HandleQueueStopped
```

IOCompleteEvent

For analog input operations that use a reference trigger whose trigger type is something other than software (none), the event IOCompleteEvent is raised when the last post-trigger sample is copied into the user buffer. This event includes the total number of samples per channel that were acquired from the time acquisition was started (with the start trigger) to the last post-trigger sample. For example, a value of 100 indicates that a total of 100 samples (samples 0 to 99) were acquired. In some cases, this message is generated well before the events BufferDoneEvent are generated. You can determine when the reference trigger occurred and the number of pre-trigger samples that were acquired by subtracting the post trigger scan count, described on page 217, from the total number of samples that were acquired. Devices that do not support a reference trigger will never receive this event for analog input operations.
For analog output operations, the event IOCompleteEvent is raised when the last data point has been output from an analog output channel. In some cases, this event is raised well after the data is transferred from the buffer (and, therefore, well after BufferDoneEvent and QueueDoneEvents are raised). Refer to page 218 for more information on buffers.

Use the IOCompleteHandler delegate with IOCompleteEvent. When IOCompleteEvent is raised, the subsystem that raised the event and the time stamp of when the event occurred are passed in the IOCompleteEventsArgs argument of the user-defined method that matches the signature of the IOCompleteHandler delegate.

You can add your own code to the event handling method to deal with this event as needed.

The following is an example of an event handling routine called HandleIOComplete that handles the event IOCompleteEvent. This event handler displays a message on the form that indicates which subsystem raised the IOCompleteEvent and at what time the event occurred:

**Visual C#**

```csharp
public void HandleIOComplete (object sender, IOCompleteEventArgs eventData)
{
    if (this.InvokeRequired)
    {
        this.Invoke( new IOCompleteHandler (HandleIOComplete),
                    new object[] {sender, eventData });
    }
    else
    {
        string msg = String.Format ("IOComplete received on subsystem {0} at time {1}", eventData.Subsystem, eventData.DateTime.ToString("T");
        statusBarPanel.Text = msg;
    }
}
```

**Visual Basic**

```vbnet
Public Sub HandleIOComplete(ByVal sender As Object, ByVal eventData As IOCompleteEventArgs)
    If Me.InvokeRequired Then
        Me.Invoke(New IOCompleteHandler(
            AddressOf HandleIOComplete),
            New Object() {sender, eventData})
    Else
        Dim msg As String = String.Format(
            "IOComplete received on subsystem {0} at time {1}"#, eventData.Subsystem, eventData.DateTime.ToString("T")
        statusBarPanel.Text = msg
    End If
End Sub 'HandleIOComplete
QueueDoneEvent

The event QueueDoneEvent is raised when no OlBuffer objects are available on the queue and the operation stops. Refer to page 218 for more information.

Use the QueueDoneHandler delegate with QueueDoneEvent. When QueueDoneEvent is raised, the subsystem that generated the event and the time stamp of when the event occurred are passed in the GeneralEventArgs argument of the user-defined method that matches the signature of the QueueDoneHandler delegate.

The following is an example of an event handling routine called HandleQueueDone that handles the event QueueDoneEvent. This event handler displays a message on the form that indicates which subsystem raised the QueueDoneEvent and at what time the event occurred:

**Visual C#**

```csharp
public void HandleQueueDone (object sender,
   GeneralEventArgs eventData)
{
   if (this.InvokeRequired)
   {
      this.Invoke(new QueueDoneHandler(HandleQueueDone),
          new object[] { sender, eventData });
   }
   else
   {
      string msg = String.Format("Queue Done received on {0} \
          element {1} at time {2}", eventData.Subsystem,
          eventData.Subsystem.Element,
          eventData.DateTime.ToString("T");
      statusBarPanel.Text = msg;
   }
}
```

**Visual Basic**

```vbnet
Public Sub HandleQueueDone(ByVal sender As Object,
   ByVal eventData As GeneralEventArgs)
If Me.InvokeRequired Then
   Me.Invoke(New QueueDoneHandler(AddressOf HandleQueueDone),
      New Object() {sender, eventData})
Else
   Dim msg As String = String.Format(
      "Queue Done received on {0} element {1} at time {2}",
      eventData.Subsystem, eventData.Subsystem.Element,
      eventData.DateTime.ToString("T");
   statusBarPanel.Text = msg
End If
End Sub 'HandleQueueDone
```
DriverRunTimeErrorEvent

The DriverRunTimeErrorEvent occurs when the device driver detects one of the following error conditions:

- **FifoOverflow** – The driver could not read data from the device FIFO (or Windows USB FIFO) fast enough, resulting in a FIFO overflow condition. To deal with this error, increase the size of the buffers, slow down the sampling rate, or stop other CPU-intensive running programs.

  **Note:** By setting the `AnalogInputSubsystem.StopOnError` property, you can determine how the subsystem operates if an overrun occurs. If `StopOnError` is True, the subsystem will automatically stop when an overrun is detected. If `StopOnError` is False, the subsystem will continue running if an overrun is detected.

- **FifoUnderflow** – The driver could not write data to the device FIFO (or Windows USB FIFO) fast enough, resulting in FIFO underflow condition. To deal with this error, increase the size of buffers, slow down the sampling rate, or stop other CPU-intensive running programs.

  **Note:** By setting the `AnalogOutputSubsystem.StopOnError` property, you can determine how the subsystem operates if an underrun occurs. If `StopOnError` is True, the subsystem will automatically stop when an underrun is detected. If `StopOnError` is False, the subsystem will continue running if an underrun is detected.

- **DeviceOverClocked** – The A/D clock (usually external clock) is running too fast on the device. To deal with this error, slow down the A/D clock.

- **TriggerError** – The driver detected a trigger on the device but did not act on it.

- **DeviceError** – Generated by the driver due to a USB bus or hardware problem. To deal with this error, stop connecting/disconnecting USB devices while streaming data to them.

Use the `DriverRunTimeErrorEventHandler` delegate with `DriverRunTimeErrorEvent`. When `DriverRunTimeErrorEvent` is raised, the subsystem that generated the event, the time stamp of when the event occurred, the error code, and the error code descriptor are passed in the `DriverRunTimeErrorEventArgs` argument of the user-defined method that matches the signature of the `DriverRunTimeErrorEventHandler` delegate.

The following is an example of an event handling routine called `HandleDriverRunTimeErrorEvent` that handles the event `DriverRunTimeErrorEvent`. This event handler displays a message on the form that indicates what error occurred, which subsystem raised the `DriverRunTimeErrorEvent`, and at what time the event occurred:
**Visual C#**

```csharp
public void HandleDriverRunTimeErrorEvent (object sender,
   DriverRunTimeErrorEventArgs eventData)
{
    if (this.InvokeRequired)
    {
        this.Invoke(new
            DriverRunTimeErrorEventHandler(
                HandleDriverRunTimeErrorEvent),
            new object[] { sender, eventData });
    }
    else
    {
        string msg = String.Format ("Error: {0}
            Occurred on subsystem {1} element {2} at time {3}",
            eventData.Message, eventData.Subsystem,
            eventData.Subsystem.Element,
            eventData.DateTime.ToString("T"));
        MessageBox.Show (msg, "Error");
    }
}
```

**Visual Basic**

```vbnet
Public Sub HandleDriverRunTimeErrorEvent(ByVal sender As Object,
   ByVal eventData As DriverRunTimeErrorEventArgs)
   If Me.InvokeRequired Then
       Me.Invoke(New DriverRunTimeErrorEventHandler(
           AddressOf HandleDriverRunTimeErrorEvent),
             New Object() {sender, eventData})
   Else
       Dim msg As String = String.Format ("Error: {0}
           Occurred on subsystem {1} element {2} at time {3}",
           eventData.Message, eventData.Subsystem,
           eventData.Subsystem.Element,
           eventData.DateTime.ToString("T"))
       MessageBox.Show(msg, "Error")
   End If
End Sub 'HandleDriverRunTimeErrorEvent
```
InterruptOnChangeEventArgs

The event InterruptOnChangeEventArgs is raised by some devices when a digital input line changes state.

Use the InterruptOnChangeHandler delegate with InterruptOnChangeEventArgs. When InterruptOnChangeEventArgs is raised, the subsystem that raised the event, the time stamp of when the event occurred, the digital lines that changed state, and the current state of the digital input port are passed in the InterruptOnChangeEventArgs argument of the user-defined method that matches the signature of the InterruptOnChangeHandler delegate.

The following is an example of an event handling routine called InterruptHandler that handles the event InterruptOnChangeEventArgs. This event handler displays a message on the form that indicates the new value of the digital input port and what digital lines changed state:

Visual C# void InterruptHandler (object sender, InterruptOnChangeEventArgs eventData) {
    if (this.InvokeRequired)
    {
        this.Invoke( new InterruptOnChangeHandler(
            InterruptHandler), new object[] { sender, eventData });
    }
    else
    {
        string sNewVal = String.Format
            ("0x{0:X}", eventData.NewValue);
        newValueTextBox.Text = sNewVal;

        sNewVal = String.Format
            ("0x{0:X}", eventData.ChangedBits);
        txtChange.Text = sNewVal;
    }
}
EventDoneEvent

The event EventDoneEvent is raised by some devices, such as the DT340, when a digital input line changes state or when an interval timer operation is complete.

Use the EventDoneHandler delegate with EventDoneEvent. When EventDoneEvent is raised, the subsystem that raised the event, the time stamp of when the event occurred, and the data associated with that event are passed in the EventDoneEventArgs argument of the user-defined method that matches the signature of the EventDoneHandler delegate.

The following is an example of an event handling routine called HandleEventDone that handles the event EventDoneEvent. This event handler displays a message on the form that indicates the count:

Visual C#
void HandleEventDone (object sender, 
   EventDoneEventArgs eventData) 
{
   if (this.InvokeRequired)
   {
      this.Invoke( new EventDoneHandler (HandleEventDone),
         new object[] {sender, eventData });
   }
   else
   {
      txtEventCount.Text = eventData.Data.ToString();
   }
}
**Visual Basic**

```vbnet
Sub HandleEventDone(ByVal sender As Object, ByVal eventData As EventDoneEventArgs)
    If Me.InvokeRequired Then
        Me.Invoke(New EventDoneHandler(
            AddressOf HandleEventDone), New Object()
            {sender, eventData})
    Else
        txtEventCount.Text = eventData.Data.ToString()
    End If
End Sub 'HandleEventDone
```

**MeasureDoneEvent**

The event MeasureDoneEvent is raised when an edge-to-edge measurement (Measure) operation is complete. Refer to page 235 for more information on edge-to-edge measurement operations.

Use the **MeasureDoneHandler** delegate with MeasureDoneEvent. When MeasureDoneEvent is raised, the subsystem that raised the event, the time stamp of when the event occurred, and the count are passed in the MeasureDoneEventArgs argument of the user-defined method that matches the signature of the **MeasureDoneHandler** delegate.

The following is an example of an event handling routine called HandleMeasureDone that handles the event MeasureDoneEvent. This event handler displays a message on the form that indicates the count:

**Visual C#**

```csharp
void HandleMeasureDone (object sender,
    MeasureDoneEventArgs eventData)
{
    if (this.InvokeRequired)
    {
        this.Invoke( new MeasureDoneHandler(
            HandleMeasureDone), new object[] { 
                sender, eventData });
    }
    else
    {
        txtEventCount.Text = eventData.Count.ToString();
    }
}
```

**Visual Basic**

```vbnet
Sub HandleMeasureDone (ByVal sender As Object,
    ByVal eventData As MeasureDoneEventArgs)
    If Me.InvokeRequired Then
        Me.Invoke(New MeasureDoneHandler(
```

270
AddressOf HandleMeasureDone),
           New Object() {sender, eventData})
Else
           txtEventCount.Text = eventData.Count.ToString()
End If
End Sub 'HandleMeasureDone

**GeneralFailureEvent**

The event GeneralFailureEvent is raised when a general library failure occurs.

Use the `GeneralFailureEventHandler` delegate with GeneralFailureEvent. When GeneralFailureEvent is raised, the subsystem that raised the event and the time stamp of when the event occurred are passed in the GeneralEventArgs argument of the user-defined method that matches the signature of the `GeneralFailureEventHandler` delegate.

You can add your own code to the handler to deal with this event as needed.

**DeviceRemovedEvent**

The event DeviceRemovedEvent is raised when a device is removed from your system while your application is running.

Use the `DeviceRemovedEventHandler` delegate with DeviceRemovedEvent. When DeviceRemovedEvent is raised, the subsystem that raised the event and the time stamp of when the event occurred are passed in the GeneralEventArgs argument of the user-defined method that matches the signature of the `DeviceRemovedEventHandler` delegate.

You can add your own code to the event handling method to deal with this event as needed.
Handling Errors

Errors are generated by the DT-Open Layers .NET Class Library as OlException objects. Each OlException object contains an OlError object, which contains the error code and its description. Your program should handle exceptions as they occur, performing the appropriate actions to deal with any errors that arise.

Refer to Appendix A for a list of error codes and messages. These values are defined as enumerations that are accessible using the OlException.ErrorCode and OlException.Message properties. If you want to determine which subsystem generated the error, use the OlException.Subsystem property.

The following example shows how to catch exceptions in your program; this example the error message is printed to text field on the form:

Visual C#
catch (OlException ex)
{
    string err = ex.Message;
    statusBarPanel.Text = err;
    return;
}

Visual Basic
Catch ex As OlException
    Dim err As String = ex.Message
    statusBarPanel.Text = err
    Return
Cleaning Up Operations

When you are finished performing data acquisition operations, clean up the memory and resources that were used by the operation by doing the following:

1. Release the simultaneous start list, if used, using the `SimultaneousStart.Clear` method.
2. Deallocate any buffers, if used. Refer to page 227 for more information.
3. Release the subsystem connection to the device using the `Dispose` method within the appropriate subsystem class.

Cleaning Up Operations ............................................... 345
Overview

To perform a data acquisition operation, you need to do the following:

1. Import the namespace for the library.
2. Get a DeviceMgr object to manage DT-Open Layers devices.
3. Get a Device object for each DT-Open Layers device that you want to use.
4. Get a subsystem of each type that you want to use.
5. Determine what channels are supported on each subsystem, and set up channel parameters.
6. Set up and configure the subsystem.
7. Perform the I/O operations.
8. Start subsystems simultaneously, if supported.
9. Auto-calibrate the subsystem, if supported.
10. Handle events.
11. Handle errors.
12. When finished, clean up the memory and resources used by the operations.

The remaining sections in this chapter describe these steps in detail.
Importing the Namespace for the Library

To use any of the classes in the OpenLayers.DeviceCollection namespace, you first need to import the namespace into your program, as follows:

**Visual C#**
using OpenLayers.DeviceCollection

**Visual Basic**
Imports OpenLayers.DeviceCollection
Getting a DeviceMgr Object

Before performing any operation using the OpenLayers.DeviceCollection namespace, you must first use the `DeviceMgr.Get` method to return a DeviceMgr object. The DeviceMgr object is responsible for managing all DT-Open Layers device collections in your system.

The following examples show how to get a DeviceMgr object:

**Visual C#**

```csharp
DeviceMgr deviceMgr = DeviceMgr.Get();
```

**Visual Basic**

```vbnet
deviceMgr As DeviceMgr = DeviceMgr.Get()
```
**Getting a Device Object**

Once you have a DeviceMgr object, use the `DeviceMgr.GetDevice` method to return a Device object for each device collection that you want to use.

**Note:** If you wish, you can also create a Device object using the `Device` constructor instead of using the `GetDevice` method.

The following examples shows how to get a Device object for the device collection named `CollectionName`:

**Visual C#**

```csharp
Device device = deviceMgr.GetDevice (CollectionName);
```

**Visual Basic**

```vbnet
device As Device = deviceMgr.GetDevice(CollectionName)
```

You can determine if a DT-Open Layers-compatible device collection is plugged into your system by using the `DeviceMgr.HardwareAvailable` method. If this method returns True, at least one DT-Open Layers-compatible device collection is plugged into your system.

To determine the names of all DT-Open Layers-compatible device collections plugged into your system, use the `DeviceMgr.GetDeviceNames` method.

You can also use the use the following properties and/or methods to return information about the specified Device object:

- **Device.CollectionDevices** property – Returns an array of Device objects for each device in the collection. The array is ordered by the collection device numbers (0 to n) with devices 0 and n being at each end of the Sync Bus chain.

- **Device.DeviceName** property – Returns the user-defined name for the device collection. You can modify this name using the DT Device Collection Manager application.

- **Device.MasterIndex** property – Returns the index of the master Device object in the CollectionDevices array.

- **Device.GetHardwareinfo** method – Returns the collection ID, number of devices in the collection, and the vendor ID for the specified device collection. See page 138 for more information on these fields.
Getting a Subsystem

The following subsystem types are defined in the OpenLayers.DeviceCollection namespace:

- **AnalogInputSubsystem** – This subsystem type represents the analog input channels of your device collection. Use this subsystem type if you want to acquire data from the analog input channels.

  If your device collection supports streaming digital input, counter/timer, and or quadrature decoder data through the analog input subsystem, use AnalogInputSubsystem to read this data.

- **AnalogOutputSubsystem** – This subsystem type represents the analog output channels of your device collection, if supported. Use this subsystem type if you want to update the values of the analog output channels.

  **Note:** The AnalogOutputSubsystem type is supported for the device collection only if the analog output subsystem of your device supports expansion through the Sync Bus. Refer to the hardware documentation for your device for more information.

If your device supports streaming digital output data through the analog output subsystem, use AnalogOutputSubsystem to update the data on the digital output ports.

Your device may support all or a subset of these functions or subsystem types. In addition, your device may support multiple instances, called elements, of the same subsystem type. Element numbering is zero-based; that is, the first instance of the subsystem is called element 0, the second instance of the subsystem is called element 1, and so on.

Once you have a Device object, you need to get a subsystem of the appropriate type for each subsystem element that you want to use. While you can do this using the constructor provided in each subsystem class, it is recommended that you use one of the following methods of the Device class:

- **Device.AnalogInputSubsystem** method – Returns an analog input subsystem for a specified element and Device object. Most DT-Open Layers device collections group all the analog input channels into one analog input subsystem element (0).

  The following example shows how to get an AnalogInputSubsystem object for element 0:

  **Visual C#**
  ```csharp
  AnalogInputSubsystem ainSS = device.AnalogInputSubsystem (0);
  ```

  **Visual Basic**
  ```vbnet
  ainSS As AnalogInputSubsystem = device.AnalogInputSubsystem(0)
  ```

- **Device.AnalogOutputSubsystem** method – Returns an analog output subsystem for a specified element and Device object. Most DT-Open Layers device collections group all the analog output channels into one analog output subsystem element (0). The following example shows how to get an AnalogOutputSubsystem object for element 0:

  **Visual C#**
  ```csharp
  AnalogOutputSubsystem aoutSS = device.AnalogOutputSubsystem (0);
  ```

  **Visual Basic**
  ```vbnet
  aoutSS As AnalogOutputSubsystem = device.AnalogOutputSubsystem(0)
  ```
You can determine the type of a specified subsystem by using the `SubsystemType` property within the appropriate subsystem class.

To return the number of elements supported by a specified subsystem type on a specified device, use the `Device.GetNumSubsystemElements` method.

You can determine the state of a subsystem using the `State` property within the appropriate subsystem class. The following states have been defined:

- **Initialized** – The subsystem has been initialized, but not configured.
- **ConfiguredForSingleValue** – The subsystem has been configured for a single-value operation.
- **ConfiguredForContinuous** – The subsystem has been configured for a continuous operation.
- **Running** – The subsystem is running.

**Note:** You can also use the `IsRunning` property within the appropriate subsystem class to determine if the subsystem is running.

- **Stopping** – The operation on the subsystem is in the process of stopping.
- **Aborting** – The operation on the subsystem is in the process of being aborted.
- **Prestarted** – The subsystem has been prestarted for a continuous simultaneous operation.
- **IOComplete** – For analog input subsystems, the final post-trigger samples has been copied to the user buffer. For analog output subsystems, the final analog output sample has been written from the FIFO on the device; this is a transient state, which may not be seen, but does occur.
**Determining the Available Channels and Setting up Channel Parameters**

When you get a subsystem of a specified type, the software automatically determines the number of available channels for the subsystem and creates a SupportedChannelInfo object for each channel. The SupportedChannelInfo object contains the following information:

- physical channel number
- logical channel number
- logical channel word
- channel name
- I/O type
- Information that pertains to voltage input channels:
  - sensor gain
  - sensor offset
- Information that pertains to accelerometer (IEPE) channels:
  - coupling
  - excitation current source
  - value for the internal excitation current source

To get a collection of SupportedChannelInfo objects, use the SupportedChannels class.

You can get the SupportedChannelInfo object for a specific channel using the SupportedChannels.GetChannelInfo method and any one of the following arguments:

- The physical channel number.
- The user-defined name of the channel.
- The subsystem type and logical channel number.
- The subsystem type, logical channel number, and logical channel word.

You can also use the SupportedChannels.Item ([]) property to return the SupportedChannelsInfo object at a specific index.

The following subsections describe the elements of the SupportedChannelsInfo class in more detail.
Physical and Logical Channels

The logical channel number, which is zero-based, maps the physical channel to the channel’s subsystem type. For example, Table 74 lists the SupportedChannels object for the analog input subsystem of a VIBbox-64 system. The VIBbox-64 collection consists of four DT9857E modules (0 to 3) and contains 64 analog input channels, four tachometers, 12 counter/timers (4 general-purpose counter/timers and 8 measure counters), and four digital input ports.

As you can see, physical channels 0 to 63 map to logical channels 0 to 15 of the analog input subsystem for each DT9857E module in the device collection. Physical channels 64 to 68 map to the extended channels (tachometer, counter/timers, and digital input port for device 0 in the device collection, physical channels 69 to 73 map to the extended channels for device 1 in the device collection, and physical channels 74 to 78 map to the extended channels for device 2 in the device collection, and physical channels 79 to 83 map to the extended channels for device 3 in the device collection.

You can determine the number of a physical channel for a given subsystem using the `SupportedChannelInfo.PhysicalChannelNumber` property.

You can determine the number of a logical channels for a given subsystem using the `SupportedChannelInfo.LogicalChannelNumber` property.

To reference a channel by number, specify either the physical channel number or the subsystem type and logical channel number.

### Logical Channel Word

Some channels, such as 32-bit counter/timers on some devices, return multi-word data. The logical channel word, which is zero-based, maps the physical channel to the data word that it returns. For example, if a 32-bit counter/timer corresponds use two physical channels, the first physical channel corresponds to logical channel word 0 (the first 16-bits of data), and the second physical channel corresponds to logical channel word 1 (the second 16-bits of data).

For channels that do not return multi-word data, the value of the logical channel word is -1.

Table 75 shows an example of the logical channel words.

You can determine the value of the logical channel word for a given channel using the `SupportedChannelInfo.LogicalChannelWord` property.

To reference a channel by logical channel word, specify the subsystem type, logical channel number, and logical channel word.

### Channel Name

By default, each channel that is listed in the `SupportedChannelInfo` class has a name that describes the subsystem type and includes the logical channel number and logical channel word, if applicable. Examples of default names include `Ain0` for analog input channel 0, `Aout1` for analog output channel 1, `Din0` for digital input channel 0, `Dout2` for digital output channel 2, `CT0 Word 1` for counter/timer channel 0 (word 1), and `Quad1 Word 0` for quadrature decoder channel 1 (word 0).

You can specify your own name for a channel using the `SupportedChannelInfo.Name` property.

To reference a channel by name, specify the name of the channel.
IOType

You can determine what kind of I/O operation is supported for a particular channel of a given subsystem using the SupportedChannelInfo.IOType property.

This property returns one of the following I/O types:

- VoltageIn
- VoltageOut
- DigitalInput
- DigitalOutput
- QuadratureDecoder
- CounterTimer
- Tachometer
- Current
- Thermocouple
- Rtd
- StrainGage
- Accelerometer
- Bridge
- Thermistor
- Resistance
- MultiSensor

**Note:** Currently, device collections support only VoltageIn and Accelerometer I/O types.

---

**Setting Up Voltage Input Channels**

To determine whether a specific channel of a device collection supports voltage inputs, use the SupportedChannelInfo.IOType property.

You can read a single voltage value from one channel using the AnalogInputSubsystem.GetSingleValueAsVolts method. Refer to page 292 for more information.

If you are acquiring data to a buffer, you can read the voltage value from the specified channels using the OIBuffer.GetDataAsVolts method. Refer to page 325 for more information.
Sensor Gain and Offset

If you want to read a value from a channel in engineering units, like pressure, and your channel supports voltage measurements only, you can specify the gain and offset for the sensor using the `SupportedChannelInfo.SensorGain` and `SupportedChannelInfo.SensorOffset` properties.

The sensor gain and offset are used to scale a sample from raw counts to a sensor format. The scaling occurs in two steps. First, the raw count value is converted to prescaled voltage using the gain applied to the input signal. Then, the prescaled voltage is scaled using the following equation:

\[ y = mx + b \]

where \( y \) is the scaled sensor value, \( m \) is the sensor gain, \( x \) is the prescaled value in voltage, and \( b \) is the sensor offset.

The following example shows how to set the sensor gain and offset of channel 0 of the analog input subsystem using the `SupportedChannels` object:

**Visual C#**

```csharp
SupportedChannelInfo Ch0Info =
    ainSS.SupportedChannels.GetChannelInfo(
        SubsystemType.AnalogInput, 0);

// Set the sensor gain and offset
Ch0Info.SensorGain = 2;
Ch0Info.SensorOffset = 10;
```

**Visual Basic**

```vbnet
Dim Ch0Info As SupportedChannelInfo =
    ainSS.SupportedChannels.GetChannelInfo(
        SubsystemType.AnalogInput, 0)

' Set the sensor gain and offset
Ch0Info.SensorGain = 2
Ch0Info.SensorOffset = 10
```

Setting Up Accelerometer (IEPE) Input Channels

To determine if the analog input subsystem supports IEPE inputs, use the `AnalogInputSubsystem.SupportsIepe` property.

For channels that support accelerometers (IEPE inputs), you can set the following properties:

- Coupling
- Excitation current source
**Coupling**

To determine if the analog input subsystem supports DC coupling (where DC offset is included), use the `AnalogInputSubsystem.SupportsDCCoupling` property. To determine if the analog input subsystem supports AC coupling (where the DC offset is removed), use the `AnalogInputSubsystem.SupportsACCoupling` property.

You can specify one of the coupling type using the `SupportedChannelInfo.Coupling` property. By default, DC coupling is used.

**Excitation Current Source Values**

To determine if the analog input subsystem supports an internal excitation current source, use the `AnalogInputSubsystem.SupportsInternalExcitationCurrentSrc` property. To determine if the analog input subsystem supports an external excitation current source, use the `AnalogInputSubsystem.SupportsExternalExcitationCurrentSrc` property.

You can specify the excitation current source (Internal, External, or Disabled) using the `SupportedChannelInfo.ExcitationCurrentSource` property. By default, the excitation current source is disabled.

If you set the excitation current source to Internal, you can also set the value of the excitation current source using the `SupportedChannelInfo.ExcitationCurrentValue` property. To determine what current source values are supported by the subsystem, use the `AnalogInputSubsystem.SupportedExcitationCurrentValues` property. By default, the first value in the list of supported values is used.
Setting Up and Configuring a Subsystem

Once you have gotten a subsystem and know about its supported channels, you can set up the subsystem for the I/O operation that you want to perform, and then configure it.

The way you set up the subsystem depends on the operation that you want to perform. Refer to the following sections for specific information on setting up I/O operations:

- For analog I/O operations, refer to page 292.
- For simultaneous operations, refer to page 330.

Call the Config method within the appropriate subsystem class to configure the subsystem before performing the I/O operation.
Performing Analog I/O Operations

Using the OpenLayers.DeviceCollection namespace in the DT-Open Layers for .NET Class Library, you can perform the following types of analog I/O operations.

- Single value analog input, described below
- Single value analog output, described on page 293
- Continuous pre- and post-trigger analog input using a start and reference trigger, described on page 298
- Continuous post-trigger analog input, described on page 300
- Continuously paced analog output, described on page 303
- Continuous waveform generation analog output, described on page 305

**Note:** On some devices, an AnalogOutputSubsystem element is used to set an analog threshold trigger; these elements support single-value analog output operations only.

### Single-Value Analog Input Operations

Single-value operations are the simplest to use but offer the least flexibility and efficiency. In a single-value analog input operation, a single data value is read from a single channel. The operation occurs immediately.

To determine if the subsystem supports single-value operations, use the `AnalogInputSubsystem.SupportsSingleValue` property. If this property returns a value of `True`, the subsystem supports single-value operations.

Once you have an AnalogInputSubsystem object, as described on page 280, and set up the channels as described on page 288, set up the AnalogInputSubsystem object for a single value operation as follows:

2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogInputSubsystem.ChannelType` property. See page 308 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogInputSubsystem.Encoding` property. See page 308 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the `AnalogInputSubsystem.VoltageRange` property. See page 309 for more information on voltage ranges.
5. (Optional) For measurements that require an excitation source (such as IEPE inputs), set the excitation voltage source for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property, and if using an internal excitation source, set the value of the internal excitation voltage source using the `AnalogInputSubsystem.ExcitationVoltageValue` property. See page 309 for more information on excitation voltage sources.

6. Configure the subsystem using the `AnalogInputSubsystem.Config` method.

7. Acquire a single value using one of the following methods:
   
   − `AnalogInputSubsystem.GetSingleValueAsRaw` – Acquires a single value from a specified analog input channel using a specified gain, and returns the value as a raw count.
   
   − `AnalogInputSubsystem.GetSingleValueAsVolts` – Acquires a single value from a specified analog input channel using a specified gain, and returns the data as a voltage.
   
   − `AnalogInputSubsystem.GetSingleValueAsSensor` – Acquires a single value from a specified analog input channel at a specified gain, and returns the data as a sensor value.

Single-value operations stop automatically when finished; you cannot stop a single-value operation in software.

Refer to the example programs `ReadSingleValueAsRaw`, `ReadSingleValueAsVolts`, and `ReadSingleValueAsSensor` to see how to perform a single-value analog input operation.

---

**Note:** After the acquisition is complete, you can convert a raw count value to voltage using the `AnalogInputSubsystem.RawValueToVolts` method or to a sensor value using the `AnalogInputSubsystem.RawToSensorValues` method. If you want to convert voltage to raw counts, you can use the `AnalogInputSubsystem.VoltsToRawValue` method.

---

### Single-Value Analog Output Operations

In a single-value analog output operation, a single data value is output from a single analog output channel. The operation occurs immediately.

To determine if the subsystem supports single-value operations, use the `AnalogOutputSubsystem.SupportsSingleValue` property. If this property returns a value of True, the subsystem supports single-value operations.

Once you have an AnalogOutputSubsystem object, as described on page 280, set up the AnalogOutputSubsystem object for a single value operation as follows:

2. (Optional) Set the channel type of the subsystem to `SingleEnded` or `Differential` using the `AnalogOutputSubsystem.ChannelType` property. See page 308 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogOutputSubsystem.Encoding` property. See page 308 for more information on data encoding.

4. (Optional) Set the voltage range of the subsystem using the `AnalogOutputSubsystem.VoltageRange` property. See page 309 for more information on voltage ranges.

5. Configure the subsystem using the `AnalogOutputSubsystem.Config` method.

6. Output a single value using one of the following methods:

   **For Devices with Multiplexed D/A architectures:**
   - `AnalogOutputSubsystem.SetSingleValueAsRaw` – Outputs a single raw count on the specified analog output channel.
   - `AnalogOutputSubsystem.SetSingleValueAsVolts` – Outputs a single voltage value on a specified analog output channel.

   **For Devices with Simultaneous D/A architectures (SupportsSetSingleValues is True):**
   - `AnalogOutputSubsystem.SetSingleValuesAsRaw` – Outputs a single raw count on each specified analog output channel. If an analog output channel is not specified, the value of the output channel will not change; the output channel maintains the last value that was written to it.
   - `AnalogOutputSubsystem.SetSingleValuesAsVolts` – Outputs a single voltage value on each specified analog output channel. If an analog output channel is not specified, the value of the output channel will not change; the output channel maintains the last value that was written to it.

**Note:** You can convert a raw count value to voltage using the `AnalogOutputSubsystem.RawValueToVolts` method. If you want to convert voltage to raw counts, you can use the `AnalogOutputSubsystem.VoltsToRawValue` method.

Single-value operations stop automatically when finished; you cannot stop a single-value operation in software.

Refer to the example programs WriteSingleValueAsRaw, WriteSingleValueAsVolts, and WriteSingleValueAsRawProgranges to see how to perform a single-value analog output operation.
Continuous, Pre- and Post-Trigger Analog Input Operations Using a Start and Reference Trigger

Note: This mode requires use of an `AnalogInputSubsystem.Trigger` object and `AnalogInputSubsystem.ReferenceTrigger` object. Some devices may not support this mode.

Use this mode when you want to acquire pre-trigger data from multiple analog input channels continuously when a specified trigger occurs and, when a reference trigger occurs, acquire a specified number of post-trigger samples.

Once you have an `AnalogInputSubsystem` object, as described on page 280, and set up the channels as described on page 288, set up the `AnalogInputSubsystem` object for a continuous operation as follows:

1. Set the `AnalogInputSubsystem.DataFlow` property to Continuous.
2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogInputSubsystem.ChannelType` property. See page 308 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwoComplement using the `AnalogInputSubsystem.Encoding` property. See page 308 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the `AnalogInputSubsystem.VoltageRange` property. See page 309 for more information on voltage ranges.
5. (Optional) For measurements that require an excitation source (such as IEPE inputs), set the excitation voltage source for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property, and if using an internal excitation source, set the value of the internal excitation voltage source using the `AnalogInputSubsystem.ExcitationVoltageValue` property. See page 309 for more information on excitation voltage sources.
6. Set up the channel list (including setting the gain and inhibit value for each entry), as described on page 310. The channel list must include at least one channel from the master device in the device collection.

Note: If you want to continuously acquire data from the digital input, counter/timer, tachometer, and/or quadrature decoder channels as part of the analog input stream, you must set up the channel list to include these channels. For counter/timer and quadrature decoder channels, you must also configure and start these subsystems before starting the analog input operation. For digital input ports, you must configure the digital input subsystem for a single-value operation before starting the analog input operation. To configure these subsystems, use the OpenLayers.Base namespace. Refer to page 229 for information on continuous digital input operations, page 232 for information on continuous counter/timer operations, page 251 for information on tachometer operations, and page 253 for information on quadrature decoder operations.
7. Set up the clock, as described on page 317.

8. Use the `AnalogInputSubsystem.Trigger.TriggerType` property to specify the trigger type that starts pre-trigger acquisition. Refer to page 318 for more information on supported trigger sources.

9. Use the `AnalogInputSubsystem.ReferenceTrigger.TriggerType` property to specify the trigger type that stops pre-trigger acquisition and starts post-trigger acquisition. Refer to page 318 for more information on supported trigger sources.

10. If the start or reference trigger type is a threshold trigger, do the following:
    a. Specify the channel to use for the threshold trigger using the
       `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` or
       Refer to page 320 for more information.
    b. Specify a voltage value for the threshold level using the
       `AnalogInputSubsystem.Trigger.Level` or
       `AnalogInputSubsystem.ReferenceTrigger.Level` property. Refer to page 320 for more information.

11. Specify the number of samples to acquire after the reference trigger occurs using the
    `AnalogInputSubsystem.ReferenceTrigger.PostTriggerScanCount` property. Refer to page 322 for more information on the post-trigger scan count.

12. Set up the input buffers, as described on page 322.

13. If your program is running under a heavy CPU load, it is recommended that you set the
    `AnalogInputSubsystem.SynchronousBufferDone` property to True for synchronous execution of each BufferDoneEvent event in a single worker thread.

15. Call the `AnalogInputSubsystem.Start` method to start the operation.

Pre-trigger acquisition begins when the start trigger is detected. When the reference trigger occurs, pre-trigger acquisition stops and post-trigger acquisition begins at the next sample. The sampled data is placed in the allocated buffer(s). The operation continues until the number of scans that you specify for `PostTriggerScanCount` has been acquired. At the point, you will get the last buffer that has valid samples; the remainder of the buffers are cancelled.
Figure 15 illustrates continuous pre- and post-trigger mode (using a start and reference trigger) with a channel list of three entries: channel 0 through channel 2. In this example, pre-trigger analog input data is acquired when the start trigger is detected. When the reference trigger occurs, the specified number of post-trigger samples (three, in this example) are acquired.

If desired, you can also stop a continuous pre- and post-trigger operation using one of the following methods:

- **AnalogInputSubsystem.Stop** – Stops the operation after the current buffer has been filled. The driver raises a BufferDoneEvent event for the completed buffer and sets the `OlBuffer.ValidSamples` property to the number of samples in the completed buffer. It then raises a BufferDoneEvent event for up to eight inprocess buffers, setting the `OlBuffer.ValidSamples` property to 0, before raising a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored. Refer to page 322 for more information on buffers, and to page 332 for information on dealing with events.

- **AnalogInputSubsystem.Abort** – Stops the operation immediately without waiting for the current buffer to be filled and sets the `OlBuffer.ValidSamples` property to the number of samples in the buffer. The driver raises a BufferDoneEvent event for up to eight inprocess buffers, setting the `OlBuffer.ValidSamples` property to 0, and then raises a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored.

- **AnalogInputSubsystem.Reset** – Stops the operation immediately without waiting for the current buffer to be filled, and reinitializes the subsystem to the default configuration.
Note: If you set the `AnalogInputSubsystem.AsynchronousStop` property to True, control returns to your program after `Stop` is called. If you set the `AsynchronousStop` property to False (the default setting) control does not return to your program after `Stop` is called until the buffer completes or 20 seconds elapses (if the buffer takes longer than 20 seconds to fill). If you try to perform another operation while the stop is in progress, an exception is raised with the error code “SubsystemStopping” and the exception message “The subsystem is in the process of stopping or aborting”.

Continuous Post-Trigger Analog Input Operations Using One Channel and One Buffer

Use this mode when you want to acquire one buffer of post-trigger data from one analog input channel.

Once you have an AnalogInputSubsystem object, as described on page 280, and set up the channels as described on page 288, perform the following steps:

1. Set the `AnalogInputSubsystem.DataFlow` property to Continuous.
2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogInputSubsystem.ChannelType` property. See page 308 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogInputSubsystem.Encoding` property. See page 308 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the `AnalogInputSubsystem.VoltageRange` property. See page 309 for more information on voltage ranges.
5. (Optional) For measurements that require an excitation source (such as IEPE inputs), set the excitation voltage source for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property, and if using an internal excitation source, set the value of the internal excitation voltage source using the `AnalogInputSubsystem.ExcitationVoltageValue` property. See page 309 for more information on excitation voltage sources.
6. Set up the channel list (including setting the gain and inhibit value for the channel, and adding the channel to the channel list), as described on page 310.
7. Set up the clock, as described on page 317.
8. Use the `AnalogInputSubsystem.Trigger.TriggerType` property to specify the post-trigger source that starts the operation. Refer to page 318 for more information on supported trigger sources.
9. If the trigger type is a threshold trigger, do the following:
   a. Specify the channel to use for the threshold trigger using the
      AnalogInputSubsystem.Trigger.ThresholdTriggerChannel property. Refer to page 320
      for more information.
   b. Specify a voltage value for the threshold level using the
      AnalogInputSubsystem.Trigger.Level property. Refer to page 320 for more
      information.

10. Call the AnalogInputSubsystem.GetOneBuffer method to acquire one buffer of
    post-trigger data from the specified channel in the channel list. You specify the number
    of samples to acquire in the call.
    This method is synchronous and returns only after the requested data has been acquired
    or the specified timeout value, in milliseconds, has been exceeded. If the buffer is not
    filled before the specified timeout value is exceeded, AnalogInputSubsystem.Abort is
    called and a TimeoutException is raised. If a GeneralFailureEvent or
    DriverRuntimeErrorEvent occurs during acquisition, an OlException with the appropriate
    error code is raised.

11. Handle the input buffer, as described on page 325.

When the trigger occurs, post-trigger acquisition begins. When the number of samples have
been acquired or the specified timeout value is exceeded, the OlBuffer object is returned.

Refer to the example program GetOneBuffer to see how to perform a continuous (post-trigger)
analog input operation using one buffer.
Continuous, Post-Trigger Analog Input Operations Using Multiple Buffers

**Note:** This mode does not support use of the `AnalogInputSubsystem.ReferenceTrigger` object. To use a ReferenceTrigger object, refer to page 298.

Use continuous post-trigger mode when you want to acquire data from multiple analog input channel continuously when a specified start trigger occurs.

To determine if the subsystem supports continuous, post-trigger analog input operations, use the `AnalogInputSubsystem.SupportsContinuous` property. If this property returns a value of True, the subsystem supports continuous post-trigger analog input operations.

Once you have an AnalogInputSubsystem object, as described on page 280, and set up the channels as described on page 288, set up the AnalogInputSubsystem object for a continuous operation as follows:

1. Set the `AnalogInputSubsystem.DataFlow` property to Continuous.
2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogInputSubsystem.ChannelType` property. See page 308 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogInputSubsystem.Encoding` property. See page 308 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the `AnalogInputSubsystem.VoltageRange` property. See page 309 for more information on voltage ranges.
5. (Optional) For measurements that require an excitation source (such as IEPE inputs), set the excitation voltage source for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property, and if using an internal excitation source, set the value of the internal excitation voltage source using the `AnalogInputSubsystem.ExcitationVoltageValue` property. See page 309 for more information on excitation voltage sources.
6. Set up the channel list (including setting the gain and inhibit value for each entry), as described on page 310. The channel list must include at least one channel from the master device in the device collection.
Note: If you want to continuously acquire data from the digital input, counter/timer, tachometer, and/or quadrature decoder channels as part of the analog input stream, you must set up the channel list to include these channels. For counter/timer and quadrature decoder channels, you must also configure and start these subsystems before starting the analog input operation. For digital input ports, you must configure the digital input subsystem for a single-value operation before starting the analog input operation. To configure these subsystems, use the OpenLayers.Base namespace. Refer to page 229 for information on continuous digital input operations, page 232 for information on continuous counter/timer operations, page 251 for information on tachometer operations, and page 253 for information on quadrature decoder operations.

7. Set up the clock, as described on page 317.

8. Use the `AnalogInputSubsystem.Trigger.TriggerType` property to specify the post-trigger source that starts the operation. Refer to page 318 for more information on supported trigger sources.

9. If the trigger type is a threshold trigger, do the following:
   a. Specify the channel to use for the threshold trigger using the `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` property. Refer to page 320 for more information.
   b. Specify a voltage value for the threshold level using the `AnalogInputSubsystem.Trigger.Level` property. Refer to page 320 for more information.

10. Set up the input buffers, as described on page 322.

11. If your program is running under a heavy CPU load, it is recommended that you set the `AnalogInputSubsystem.SynchronousBufferDone` property to True for synchronous execution of each BufferDoneEvent event in a single worker thread.

12. Configure the subsystem using the `AnalogInputSubsystem.Config` method.

13. Call the `AnalogInputSubsystem.Start` method to start the continuous post-trigger operation.

When the post-trigger is detected, the device cycles through the channel list, acquiring the value for each ChannelListEntry object in the channel list; this process is defined as a scan. The device then wraps to the start of the channel list and repeats the process continuously until either the allocated buffers are filled or you stop the operation. The event BufferDoneEvent is generated as each buffer is filled with analog input data; refer to page 332 for information on dealing with events and reading the data in the buffer.

Figure 16 illustrates continuous post-trigger mode using a channel list of three entries: channel 0, channel 1, and channel 2. In this example, post-trigger analog input data is acquired on each clock pulse of the A/D sample clock. The device wraps to the beginning of the channel list and repeats continuously.
To stop a continuous post-trigger operation, use one of the following methods:

- **AnalogInputSubsystem.Stop** – Stops the operation after the current buffer has been filled. The driver raises a BufferDoneEvent event for the completed buffer and sets the OlBuffer.ValidSamples property to the number of samples in the completed buffer. It then raises a BufferDoneEvent event for up to eight inprocess buffers, setting the OlBuffer.ValidSamples property to 0, before raising a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored. Refer to page 322 for more information on buffers, and to page 332 for information on dealing with events.

- **AnalogInputSubsystem.Abort** – Stops the operation immediately without waiting for the current buffer to be filled and sets the OlBuffer.ValidSamples property to the number of samples in the buffer. The driver raises a BufferDoneEvent event for up to eight inprocess buffers, setting the OlBuffer.ValidSamples property to 0, and then raises a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored.

- **AnalogInputSubsystem.Reset** – Stops the operation immediately without waiting for the current buffer to be filled, and reinitializes the subsystem to the default configuration.

**Notes:** If you set the AnalogInputSubsystem.AsynchronousStop property to True, control returns to your program after Stop is called. If you set the AsynchronousStop property to False (the default setting) control does not return to your program after Stop is called until the buffer completes or 20 seconds elapses (if the buffer takes longer than 20 seconds to fill). If you try to perform another operation while the stop is in progress, an exception is raised with the error code "SubsystemStopping," and the exception message "The subsystem is in the process of stopping or aborting".

Refer to the example programs ReadBufferedDataAsRaw, ReadBufferedDataAsRawDigTrigger, ReadBufferedDataAsVolts, ReadBufferedDataAsSensor, and ReadBufferedDataIntoOscilloscope to see how to perform a continuous (post-trigger) analog input operation.
Using the OpenLayers.DeviceCollection Namespace

Continuously Paced Analog Output Operations

Use continuously paced output mode if you want to accurately control the period between conversions of individual analog output channels in the channel list.

To determine if the subsystem supports continuous analog output operations, use the AnalogOutputSubsystem.SupportsContinuous property. If this property returns a value of True, the subsystem supports continuously paced analog output operations.

Once you have an AnalogOutputSubsystem object, as described on page 280, set up the AnalogOutputSubsystem object for a continuous operation as follows:

1. Set the AnalogOutputSubsystem.DataFlow property to Continuous.
2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the AnalogOutputSubsystem.ChannelType property. See page 308 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the AnalogOutputSubsystem.Encoding property. See page 308 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the AnalogOutputSubsystem.VoltageRange property. See page 309 for more information on voltage ranges.
5. Set up the channel list, as described on page 310. The channel list must include at least one channel from the master device in the device collection.

Note: If you want to continuously update the digital output channels as part of the analog output stream, you must set up the channel list to include the digital output port. In addition, you must configure the digital output subsystem for a single-value operation using the OpenLayers.Base namespace before starting the analog output operation. Refer to page 229 for information on configuring the digital output subsystem.

6. (Optional) Set up the clock, as described on page 317.
7. (Optional) Use the AnalogOutputSubsystem.Trigger.TriggerType property to specify the trigger source that starts the operation. Refer to page 318 for more information on supported trigger sources.
8. If the trigger type is a threshold trigger, do the following:
   a. Specify the channel to use for the threshold trigger using the AnalogOutputSubsystem.Trigger.ThresholdTriggerChannel property. Refer to page 320 for more information.
   b. Specify a voltage value for the threshold level using the AnalogOutputSubsystem.Trigger.Level property. Refer to page 320 for more information.
9. Set the AnalogOutputSubsystem.WrapSingleBuffer property to False (the default value) to specify a buffer wrap mode of none. In this mode, the operation continues indefinitely as long as you process the buffers ad put them back on the queue in a timely manner.
10. Use software to fill the output buffer with the values that you want to write to the analog output channels and to the digital output port, if applicable. Refer to page 322 for more information on output buffers.

11. Configure the subsystem using the `AnalogOutputSubsystem.Config` method.

12. Call the `AnalogOutputSubsystem.Start` method to start the continuous analog output operation.

When it detects the appropriate trigger, the device starts writing output values to the channels, as determined by the channel list. The operation repeats continuously until either all the data is output from the buffers or you stop the operation. The event `BufferDoneEvent` occurs as each OliBuffer object is completed. If no buffers are available on the queue, the operation stops, and the event `QueueDoneEvent` is raised. Refer to page 322 for more information about buffers.

Make sure that the host computer transfers data to the output channel list fast enough so that the list always has data to output; otherwise, the event `DriverRunTimeErrorEvent` is raised. Refer to page 341 for more information on this event.

If your device supports it, you can mute the output, which attenuates the output voltage to 0 V by calling `AnalogOutputSubsystem.Mute`. This does not stop the analog output operation; instead, the analog output voltage is reduced to 0 V over a hardware-dependent number of samples. You can unmute the output voltage to its current level by calling `AnalogOutputSubsystem.UnMute`. To determine if muting and unmoming are supported by your device, read the value of the `AnalogOutputSubsystem.SupportsMute` property. If this value is True, muting and unmouting are supported.

To stop a continuous analog output operation, do not send new data to the device or use one of the following methods:

- `AnalogOutputSubsystem.Stop` – Stops the operation after all the data in the current buffer has been output. The driver raises a BufferDoneEvent event for the completed buffer and up to eight inprocess buffers, before raising a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored. Refer to page 322 for more information on buffers.

- `AnalogOutputSubsystem.Abort` – Stops the operation immediately without waiting for the data in the current buffer to be output. The driver raises a BufferDoneEvent event for the partially completed buffer and up to eight inprocess buffers, before raising a QueueStoppedEvent event. All subsequent triggers are ignored.

- `AnalogOutputSubsystem.Reset` – Stops the operation immediately without waiting for the data in the current buffer to be output, and reinitializes the subsystem to the default configuration.
Notes: If you set the `AnalogOutputSubsystem.AsynchronousStop` property to True, control returns to your program after `Stop` is called. If you set the `AsynchronousStop` property to False (the default setting) control does not return to your program after `Stop` is called until the buffer completes or 20 seconds elapses (if the buffer takes longer than 20 seconds to be output).

If you try to perform another operation while the stop is in progress, an exception is raised with the error code "SubsystemStopping" and the exception message "The subsystem is in the process of stopping or aborting".

Refer to the example program WriteBufferedDataAsVolts to see how to perform a continuously paced analog output operation.

**Continuous Waveform Generation Operations**

Use waveform generation mode if you want to output a waveform repetitively to analog output channels and, if supported, digital output ports, as specified in the ChannelList object.

To determine if the subsystem supports waveform generation operations, use the following properties:

- `AnalogOutputSubsystem.SupportsContinuous` property – If this property returns a value of True, continuous output operations are supported. This is a requirement for waveform generation operations.
- `AnalogOutputSubsystem.SupportsWrapSingle` property – If this property returns a value of True, the device driver will output data continuously from the first buffer queued to the analog output subsystem. This is a requirement for waveform generation operations. Refer to page 322 for more information on buffers.
- `AnalogOutputSubsystem.SupportsWaveformModeOnly` property – If this property returns a value of True, the device driver will output a waveform continuously from the onboard FIFO only. Set the `AnalogOutputSubsystem.WrapSingleBuffer` property to True. In addition, set the buffer size to be less than or equal to the FIFO size specified by the `AnalogOutputSubsystem.FifoSize` property. Refer to page 322 for more information on buffers.

Once you have an AnalogOutputSubsystem object, as described on page 280, set up the AnalogOutputSubsystem object for a continuous operation as follows:

1. Set the `AnalogOutputSubsystem.DataFlow` property to Continuous.
2. (Optional) Set the channel type of the subsystem to SingleEnded or Differential using the `AnalogOutputSubsystem.ChannelType` property. See page 308 for more information on channel types.
3. (Optional) Set the data encoding of the subsystem to Binary or TwosComplement using the `AnalogOutputSubsystem.Encoding` property. See page 308 for more information on data encoding.
4. (Optional) Set the voltage range of the subsystem using the \texttt{AnalogOutputSubsystem.VoltageRange} property. See page 309 for more information on voltage ranges.

5. Set up the channel list, as described on page 310. The channel list must include at least one channel from the master device in the device collection.

\textbf{Note}: If you want to continuously update the digital output channels as part of the analog output stream, you must set up the channel list to include the digital output port. In addition, you must configure the digital output subsystem for a single-value operation using the \texttt{OpenLayers.Base} namespace before starting the analog output operation. Refer to page 229 for information on configuring the digital output subsystem.

6. (Optional) Set up the clock, as described on page 317.

7. (Optional) Use the \texttt{AnalogOutputSubsystem.Trigger.TriggerType} property to specify the trigger source that starts the operation. Refer to page 318 for more information on supported trigger sources.

8. If the trigger type is a threshold trigger, do the following:
   a. Specify the channel to use for the threshold trigger using the \texttt{AnalogOutputSubsystem.Trigger.ThresholdTriggerChannel} property. Refer to page 320 for more information.
   b. Specify a voltage value for the threshold level using the \texttt{AnalogOutputSubsystem.Trigger.Level} property. Refer to page 320 for more information.

9. Set the \texttt{AnalogOutputSubsystem.WrapSingleBuffer} property to True, so that a single buffer is reused.

10. Use software to fill the output buffer with the values that you want to write to the analog output channels and to the digital output port, if applicable. Refer to your device documentation for details on the waveform pattern that you can specify and to page 322 for more information on output buffers.

\textbf{Note}: For devices that have a FIFO onboard for waveform generation operations, the device driver downloads the buffer into the FIFO on the device if the size of the buffer is less than or equal to the FIFO size. The driver (or device) outputs the data starting from the first location in the FIFO. When it reaches the end of the FIFO, the driver (or device) continues outputting data from the first location of the FIFO and the process continues indefinitely until you stop it.

You can determine the size of the FIFO on the device using the \texttt{AnalogOutputSubsystem.FifoSize} property. This property returns the actual FIFO size in kilobytes.

11. Configure the subsystem using the \texttt{AnalogOutputSubsystem.Config} method.

12. Call the \texttt{AnalogOutputSubsystem.Start} method to start the continuous analog output operation.
When it detects a trigger, the host computer writes the pattern in the buffer to specified output channels, as determined by the channel list.

If your device supports it, you can mute the output, which attenuates the output voltage to 0 V by calling `AnalogOutputSubsystem.Mute`. This does not stop the analog output operation; instead, the analog output voltage is reduced to 0 V over a hardware-dependent number of samples. You can unmute the output voltage to its current level by calling `AnalogOutputSubsystem.UnMute`. To determine if muting and unmuting are supported by your device, read the value of the `AnalogOutputSubsystem.SupportsMute` property. If this value is True, muting and unmuting are supported.

To stop a continuous analog output operation, do not send new data to the device or use one of the following methods:

- **AnalogOutputSubsystem.Stop** – Stops the operation after all the data in the current buffer has been output. The driver raises a BufferDoneEvent event for the completed buffer and up to eight inprocess buffers, before raising a QueueStoppedEvent event. All subsequent triggers or retriggers are ignored. Refer to page 322 for more information on buffers.

- **AnalogOutputSubsystem.Abort** – Stops the operation immediately without waiting for the data in the current buffer to be output. The driver raises a BufferDoneEvent event for the partially completed buffer and up to eight inprocess buffers, before raising a QueueStoppedEvent event. All subsequent triggers are ignored.

- **AnalogOutputSubsystem.Reset** – Stops the operation immediately without waiting for the data in the current buffer to be output, and reinitializes the subsystem to the default configuration.

**Notes:** If you set the `AnalogOutputSubsystem.AsynchronousStop` property to True, control returns to your program after `Stop` is called. If you set the `AsynchronousStop` property to False (the default setting) control does not return to your program after `Stop` is called until the buffer completes or 20 seconds elapses (if the buffer takes longer than 20 seconds to be output).

If you try to perform another operation while the stop is in progress, an exception is raised with the error code “SubsystemStopping” and the exception message “The subsystem is in the process of stopping or aborting”.
Setting the Channel Type

The DT-Open Layers for .NET Class Library supports the following channel types for a specified analog I/O subsystem:

- SingleEnded – Use this configuration when you want to measure high-level signals, noise is insignificant, the source of the input is close to the device, and all the input signals are referred to the same common ground.

To determine if the subsystem supports the single-ended channel type, use the SupportsSingleEnded property of the appropriate subsystem. If this property returns a value of True, the subsystem supports single-ended inputs.

To determine how many single-ended channels are supported by the subsystem, use the MaxSingleEndedChannels property of the appropriate subsystem.

- Differential – Use this configuration when you want to measure low-level signals (less than 1 V), you are using an A/D converter with high resolution (greater than 12 bits), noise is a significant part of the signal, or common-mode voltage exists.

To determine if the subsystem supports the differential channel type, use the SupportsDifferential property of the appropriate subsystem. If this property returns a value of True, the subsystem supports differential inputs.

To determine how many differential channels are supported by the subsystem, use the MaxDifferentialChannels property of the appropriate subsystem.

Set and/or return the channel type using the ChannelType property of the appropriate subsystem.

Note: For pseudo-differential analog inputs, specify the single-ended channel type; in this case, how you wire these signals determines the configuration. This option provides less noise rejection than the differential configuration, but twice as many analog input channels.

For older model devices, this setting is jumper-selectable and must be specified in the driver configuration dialog.

Setting the Data Encoding

Two data encoding types are available: binary and twos complement.

To determine if your subsystem supports binary data encoding, use the SupportsBinaryEncoding property of the appropriate subsystem. If this property returns a value of True, the subsystem supports binary data encoding.

To determine if your subsystem supports twos complement data encoding, use the SupportsTwosCompEncoding property of the appropriate subsystem. If this property returns a value of True, the subsystem supports twos complement data encoding.

Use the Encoding property of the appropriate subsystem to specify the data encoding type.
Setting the Voltage Range

To determine how many ranges the subsystem supports, use the `NumberOfRanges` property of the appropriate subsystem.

To determine all the available voltage ranges for your subsystem, use the `SupportedVoltageRanges` property of the appropriate subsystem.

Some analog output subsystems support both voltage and current output channels. To determine if the subsystem supports current outputs, use the `AnalogOutputSubsystem.SupportsCurrentOutput` property.

Use the `VoltageRange` property of the appropriate subsystem to set or return the voltage range for the subsystem.

**Note:** If you are using a current output channel, determine how the voltage range maps to your current output range and write the appropriate voltage to the output channel.

The following example shows how to set the voltage range for an analog input subsystem to the first range in the list of supported voltage ranges:

**Visual C#**

```csharp
ainSS.VoltageRange = ainSS.SupportedVoltageRanges[0];
```

**Visual Basic**

```vbnet
ainSS.VoltageRange = ainSS.SupportedVoltageRanges(0)
```

Setting the Excitation Voltage Source and Value

To determine if the analog input subsystem supports an internal excitation voltage source, use the `AnalogInputSubsystem.SupportsInternalExcitationVoltageSrc` property. To determine if the analog input subsystem supports an external excitation voltage source, use the `AnalogInputSubsystem.SupportsExternalExcitationVoltageSrc` property.

You specify the excitation voltage source to use (Internal, External, or Disabled) for the subsystem using the `AnalogInputSubsystem.ExcitationVoltageSource` property. By default, the excitation voltage source is disabled.

If you set the excitation voltage source to Internal, you can also set the value of the excitation voltage source using the `SupportedChannelInfo.ExcitationVoltageValue` property.

You can determine the minimum allowable value for the internal excitation voltage source using the `AnalogInputSubsystem.MinExcitationVoltageValue` property. Similarly, you can determine the maximum allowable value for the internal excitation voltage source using the `AnalogInputSubsystem.MaxExcitationVoltageValue` property.
Setting up the Channel List

**Note:** Single-value operations do not use a channel list.

If you want to acquire data from or update multiple channels, you need to use a continuous operation mode and specify the channels that you want to sample (and the order in which to sample them) in a ChannelList object.

Channels are sampled or updated in order from the first entry to the last entry in the ChannelList object. Channel numbering is zero-based; that is, the first entry in the ChannelList is at index 0, the second entry is at index 1, and so on.

The ChannelList property is accessible using any subsystem class whose SupportsContinuous property is True. Typically, a ChannelList is used with the AnalogInputSubsystem and AnalogOutputSubsystem classes.

For an analog input subsystem, you can specify analog input channels, as well as digital inputs, counter/timers, and/or quadrature decoders in the ChannelList object, if your device supports it. Similarly, for an analog output subsystem, you can specify analog output channels as well as digital outputs in the ChannelList object, if your device supports it. Refer to page 282 for more information on available channels.

**Note:** For a device collection, the channel list must include at least one channel from the master device in the device collection.

You can add sequential channels (such as channels 0, 1, 2, 3) or random channels (such as channels 2, 9, 7) to the ChannelList object, and can specify a channel more than once in the list (such as channels 1, 2, 1), if your device supports it.

Other devices may limit the order in which you can enter a channel in the channel list. See the user’s manual for your device to determine any channel ordering limitations.

The following example shows a ChannelList that contains four channels. Channel 1 is sampled first, followed by channel 2, channel 1 again, and then channel 0:

Adding Channels to a Channel List

The **ChannelList.Add** method adds a channel to the end of the ChannelList object, and returns the index of the added channel. You can specify the channel to add in one of the following ways:

- By physical channel number
- By channel name
- By ChannelListEntry object

The following sections describe these methods.

Adding Channels By Physical Channel Number

This method is the simplest way to add channels into the ChannelList object, particularly if you are adding channels that are native to the subsystem type (such as analog input channels on an analog input subsystem).

For native channels, the physical channel number always equals the logical channel number. While non-native channels, such as digital inputs that are streamed through the analog input subsystem, can also be added this way, the physical channel number is not the same as the logical channel number, so you may find it easier to add the channel by name or by ChannelListEntry object instead.

A new ChannelListEntry object is returned for each physical channel that is added this way. Refer to page 314 for more information on ChannelListEntry objects.

The following example shows how to use the **Add** method to add physical channel 0 to the end of a ChannelList for an analog input subsystem:

**Visual C#**

```csharp
ch = AinSS.ChannelList.Add(0);
```

**Visual Basic**

```vbnet
ch = AinSS.ChannelList.Add(0)
```

Adding Channels By Channel Name

The channel name is the name that you assigned to the channel using the SupportedChannelInfo class, described on page 282. A new ChannelListEntry object is returned for each channel that is added this way. Refer to page 314 for more information on ChannelListEntry objects.

The following example shows how to use the **Add** method to add a channel named Sensor to the end of a ChannelList for an analog input subsystem:
Visual C#  
// Specify the name Sensor for the first  
// analog input channel.  
ainSS.SupportedChannels[0].Name = "Sensor";  
// Add the channel named Sensor to the ChannelList  
ch = ainSS.ChannelList.Add("Sensor");

Visual Basic  
'Specify the name Sensor for the first  
'analog input channel.  
ainSS.SupportedChannels(0).Name = "Sensor"  
ch = AinSS.ChannelList.Add("Sensor")

Adding Channels By ChannelListEntry Object  
This method is useful if you want a more generic approach to adding channels. This approach  
frees you from keeping track of physical channel numbers and their names.

To get a ChannelListEntry object, use the ChannelListEntry constructor within the  
ChannelListEntry class, specifying the SupportedChannelInfo object for the channel that you  
want to sample or update. See page 282 for more information on SupportedChannelInfo  
objects.

This example creates a ChannelListEntry called Ch0 for physical channel 0 of the analog input  
subsystem, using all the information contained in SupportedChannelInfo for that channel.

Visual C#  
ChannelListEntry Ch0 = new ChannelListEntry (  
    ainSS.SupportedChannels.GetChannelInfo  
        (SubsystemType.AnalogInput, 0 ));

Visual Basic  
Dim Ch0 As New ChannelListEntry (  
    ainSS.SupportedChannels.GetChannelInfo  
        (SubsystemType.AnalogInput, 0 ))

Note: It is recommended that you set the gain (see page 315) and inhibition value (page 316)  
for each ChannelListEntry object after you create it. However, it is possible to set or change  
these values after the ChannelListEntry object is added to the ChannelList.

The following example shows how to use the Add method to add ChannelListEntry object  
Ch0 to the end of a ChannelList:

Visual C#  
AinSS.ChannelList.Add(Ch0);

Visual Basic  
AinSS.ChannelList.Add(Ch0)
**Inserting Channels in the Channel List**

The `ChannelList.Insert` method inserts a channel at the specified index of a `ChannelList` object, incrementing all higher index entries by 1, and returns the index of the added channel. You can specify the channel to insert in one of the following ways:

- By physical channel number
- By channel name
- By `ChannelListEntry` object

The following sections describe these methods.

**Inserting a Channel By Physical Channel Number**

This method is the simplest way to insert channels into the `ChannelList` object, particularly if you are inserting channels that are native to the subsystem type (such as analog input channels on an analog input subsystem).

For native channels, the physical channel number always equals the logical channel number. While non-native channels, such as digital inputs that are streamed through the analog input subsystem, can also be inserted this way, the physical channel number is not the same as the logical channel number, so you may find it easier to insert the channel by name or by `ChannelListEntry` object instead.

A new `ChannelListEntry` object is returned for each physical channel that is inserted this way. Refer to page 314 for more information on `ChannelListEntry` objects.

The following example shows how to use the `Insert` method to insert physical channel 3 at index 0 of the `ChannelList` for an analog input subsystem. The channel that was formally at index 0 is now at index 1.

**Visual C#**

```csharp
ch = AinSS.ChannelList.Insert(0, 3);
```

**Inserting a Channel By Channel Name**

The channel name is the name that you assigned to the channel using the `SupportedChannelInfo` class, described on page 282. A new `ChannelListEntry` object is returned for each channel that is inserted this way. Refer to page 314 for more information on `ChannelListEntry` objects.

The following example shows how to use the `Insert` method to insert a channel named `Ain3` at index 0 of the `ChannelList` for an analog input subsystem. The channel that was formally at index 0 is now at index 1.

**Visual C#**

```csharp
ch = AinSS.ChannelList.Insert(0, "Ain3");
```
Inserting a Channel By ChannelListEntry Object

This method is useful if you want a more generic approach to inserting channels. This approach frees you from keeping track of physical channel numbers and their names.

To get a ChannelListEntry object, use the ChannelListEntry constructor within the ChannelListEntry class, specifying the SupportedChannelInfo object for each channel that you want to sample or update. See page 282 for more information on SupportedChannelInfo objects.

This example creates a ChannelListEntry called Ch3 for physical channel 3 of the analog input subsystem, using all the information contained in SupportedChannelInfo for that channel.

Visual C#
ChannelListEntry Ch3 = new ChannelListEntry (  
    ainSS.SupportedChannels.GetChannelInfo  
    (SubsystemType.AnalogInput, 3 ));

Visual Basic
Dim Ch3 As New ChannelListEntry (  
    ainSS.SupportedChannels.GetChannelInfo  
    (SubsystemType.AnalogInput, 3 ))

Note: It is recommended that you set the gain (see page 315) and inhibition value (page 316) for each ChannelListEntry object after you create it. However, it is possible to set or change these values after the ChannelListEntry object is added to the ChannelList.

The following example shows how to use the Insert method to insert ChannelListEntry object Ch3 at index 0 of the ChannelList. The channel that was formally at index 0 is now at index 1.

Visual C#
AinSS.ChannelList.Insert(0, Ch3);

Visual Basic
AinSS.ChannelList.Insert(0, Ch3)

Replacing Channels in the ChannelList

The ChannelList.Item ([ ]) property replaces a ChannelListEntry object at the specified index of the ChannelList. An exception is raised if an entry does not exist at the specified index.

The following example shows how to use the Item ([ ]) property to replace the ChannelListEntry object at index 1 of the ChannelList with ChannelListEntry object Ch3:

Visual C#
AinSS.ChannelList[1] = Ch3;
Visual Basic
AinSS.ChannelList(1) = Ch3

**Removing Channels from the Channel List**

To remove a ChannelListEntry from the ChannelList object, use the `ChannelList.Remove` method. This method removes the first instance of the specified ChannelListEntry object from the ChannelList object, decrementing all higher index entries by 1.

The following example shows how to remove the first instance of ChannelListEntry object Ch0 from the ChannelList object using the `Remove` method:

**Visual C#**
AinSS.ChannelList.Remove(Ch0);

**Visual Basic**
AinSS.ChannelList.Remove(Ch0)

**Setting the Gain of a ChannelListEntry**

The voltage range divided by the gain determines the effective range for a channel. For example, if your device provides a voltage range of ±10 V and you want to measure a ±1.5 V signal, specify a range of ±10 V and a gain of 4; the effective input range for this channel is then ±2.5 V (±10/4), which provides the best sampling accuracy for that channel.

To determine if the subsystem supports programmable gain, use the `SupportsProgrammableGain` property of the appropriate subsystem. If this property returns a value of True, programmable gain is supported.

To determine the number of gains the subsystem supports, use the `NumberOfSupportedGains` property of the appropriate subsystem. To list all of the gain values supported by the subsystem, use the `SupportedGains` property.

The simplest way to specify the gain for a channel is by using a single-value operation. (In this case, a ChannelListEntry object is not used.) Refer to page 292 for more information on single-value analog input operations; refer to page 293 for more information on single-value analog output operations.

If you are using a ChannelListEntry object, specify or return the gain for each ChannelListEntry object using the `ChannelListEntry.Gain` property.

This example shows how to apply a gain of 2 to a ChannelListEntry called Ch0.

**Visual C#**
Ch0.Gain = 2;

**Visual Basic**
Ch0.Gain = 2
You can also apply gain to a ChannelListEntry in the ChannelList, as shown below; this example applies a gain of 2 to the ChannelListEntry at index 0 of the ChannelList:

**Visual C#**
AinSS.ChannelList[0].Gain = 2;

**Visual Basic**
AinSS.ChannelList(0).Gain = 2

---

**Note:** The driver sets the actual gain as closely as possible to the number specified. You can read back the exact gain after configuring the subsystem using the **Gain** property. If your subsystem does not support programmable gain, enter a value of 1 (the default value) for the gain.

---

**Inhibiting Channels in a Channel List**

If supported by your subsystem, you can inhibit data from being returned by the ChannelListEntry object. This feature is useful if you want to discard values that are acquired by specific channels.

To determine if a subsystem supports inhibition, use the **SupportsChannelListInhibit** property inherited from the SubsystemBase class. If this property returns a value of True, the subsystem supports channel inhibition.

Using the **Inhibit** property of the ChannelListEntry class, you can enable or disable inhibition for each ChannelListEntry object. If you set this property to True, the acquired value is discarded after the channel entry is sampled. If you set this property to False (the default value), the acquired value is stored after the channel entry is sampled.

This example shows how to set the channel inhibit value of the ChannelListEntry called Ch0 to True:

**Visual C#**
Ch0.Inhibit = 1;

**Visual Basic**
Ch0.Inhibit = 1

You can also set the inhibit value of a ChannelListEntry in the ChannelList, as shown below; this example sets the inhibit value to True for the ChannelListEntry at index 3 of the ChannelList:

**Visual C#**
AinSS.ChannelList[3].Inhibit = 1;

**Visual Basic**
AinSS.ChannelList(3).Inhibit = 1
**Getting Information about Channels in the ChannelList Object**

You can get information about the contents of a ChannelList object using the following methods:

- **ChannelList.Contains** method – Determines whether a specified ChannelListEntry object is contained in the ChannelList.

- **ChannelList.IndexOf** method – Searches for a specified channel (specified by physical channel or ChannelListEntry object) in the ChannelList and returns the zero-based index of the first occurrence within the ChannelList.

- **ChannelList.CGLDepth** property – Returns the maximum number of channels or ChannelListEntry objects that the ChannelList can contain.

**Setting up a Clock Source**

The OpenLayers.DeviceCollection namespace defines internal and external clock sources, described in the following subsections. Note that single-value operations do not use clocks.

---

**Note:** Some subsystems allow you to read or update multiple channels on a single clock pulse. You can determine whether multiple channels are read or updated on a single clock pulse by using the `Clock.SupportsSimultaneousClocking` property.

---

**Internal Clock Source**

The internal clock is the clock source on the device that paces data acquisition or output for each ChannelListEntry object in the channel list.

To determine if the subsystem supports an internal clock, use the `Clock.SupportsInternalClock` property. If this property returns a value of True, an internal clock is supported.

To determine the maximum frequency supported by the internal clock, use the `Clock.MaxFrequency` property. To determine the minimum frequency supported by the internal clock, use the `Clock.MinFrequency` property.

Specify the clock source as internal using the `Clock.Source` property. Then, use the `Clock.Frequency` property to specify the frequency at which to pace the operation.
Note: According to sampling theory (Nyquist Theorem), you should specify a frequency for an A/D signal that is at least twice as fast as the input’s highest frequency component. For example, to accurately sample a 20 kHz signal, specify a sampling frequency of at least 40 kHz. Doing so avoids an error condition called aliasing, in which high frequency input components erroneously appear as lower frequencies after sampling.

The driver sets the frequency of the internal clock as close as possible to the value that you specified in the Frequency property. You can determine the actual frequency that was set on the hardware by reading the value of the Frequency property after the subsystem has been configured (using the Config method).

**External Clock Source**

The external clock is a clock source attached to the device that paces data acquisition or output for each channel in the channel list. This clock source is useful when you want to pace at rates not available with the internal clock or if you want to pace at uneven intervals.

To determine if the subsystem supports an external clock, use the Clock.SupportsExternalClock property. If this property returns a value of True, an external clock is supported.

To determine the maximum external clock divider that the subsystem supports, use the Clock.MaxExtClockDivider property. To determine the minimum external clock divider that the subsystem supports, use the Clock.MinExtClockDivider property.

Specify the clock source as external using the Clock.Source property. Then, use the Clock.ExtClockDivider property to set or get the clock divider that is used to determine the frequency of the external clock source. The frequency of the external clock input divided by the external clock divider determines the frequency at which to pace the operation.

**Setting Up a Trigger Type**

Note: Single-value operations do not use triggers.

The OpenLayers.DeviceCollection namespace provides the Trigger class that can be used to set up a start trigger, and the ReferenceTrigger class that can be used to set up a reference trigger, if supported by your device. The following trigger types are available for the start and reference triggers:

- Software
- TTLPos
- TTLNeg
- ThresholdPos
- ThresholdNeg
- DigitalEvent

For devices that support a start trigger and reference trigger for performing continuous pre-and post-trigger analog input operations, specify the start trigger type using the `AnalogInputSubsystem.Trigger.TriggerType` property and specify the reference trigger type using the `AnalogInputSubsystem.ReferenceTrigger.TriggerType` property; refer to page 298 for more information on pre- and post-trigger operations using a start and reference trigger.

For devices that support continuous post-trigger operations without using a reference trigger, specify the post-trigger source using the `AnalogInputSubsystem.Trigger.TriggerType` property; refer to page 300 for more information on post-trigger operations.

The following subsections describe these trigger sources. Note that you cannot specify a trigger source for single-value operations.

**Software Trigger Source**

A software trigger occurs when you start the operation; internally, the computer writes to the device to begin the operation.

To determine if the subsystem supports a software trigger for the start trigger, use the `Trigger.SupportsSoftwareTrigger` property. If this property returns a value of True, a software trigger is supported.

To determine if the subsystem supports a software trigger for the reference trigger, use the `ReferenceTrigger.SupportsSoftwareTrigger` property. If this property returns a value of True, a software trigger is supported.

**TTLPos Trigger Source**

The TTLPos trigger source is an external digital (TTL) signal attached to the device. The trigger occurs when the device detects a transition on the rising edge of the digital TTL signal.

To determine if the subsystem supports a TTLPos trigger for a start trigger, use the `Trigger.SupportsPosExternalTTLTrigger` property. If this property returns a value of True, a TTLPos trigger is supported.

To determine if the subsystem supports a TTLPos trigger for a reference trigger, use the `ReferenceTrigger.SupportsPosExternalTTLTrigger` property. If this property returns a value of True, a TTLPos trigger is supported.

To determine if the subsystem supports a TTLPos trigger for a single-value operation, use the `Trigger.SupportsSvPosExternalTTLTrigger` property. If this property returns a value of True, a TTLPos trigger is supported.
**TTLNeg Trigger Source**

The TTLNeg trigger source is an external digital (TTL) signal attached to the device. The trigger occurs when the device detects a transition on the falling edge of the digital TTL signal.

To determine if the subsystem supports a TTLNeg trigger for a start trigger, use the `Trigger.SupportsNegExternalTTLTrigger` property. If this property returns a value of True, a TTLNeg trigger is supported.

To determine if the subsystem supports a TTLNeg trigger for a reference trigger, use the `ReferenceTrigger.SupportsNegExternalTTLTrigger` property. If this property returns a value of True, a TTLNeg trigger is supported.

To determine if the subsystem supports a TTLNeg trigger for a single-value operation, use the `Trigger.SupportsSvNegExternalTTLTrigger` property. If this property returns a value of True, a TTLNeg trigger is supported.

**ThresholdPos Trigger Source**

A threshold trigger is generally either an analog signal from an analog input channel or an external analog signal attached to the device. A positive analog threshold (ThresholdPos) trigger occurs when the device detects a positive-going signal that crosses a threshold value.

To determine if the subsystem supports a ThresholdPos trigger for the start trigger, use the `Trigger.SupportsPosThresholdTrigger` property. If this property returns a value of True, a ThresholdPos trigger is supported.

To determine if the subsystem supports a ThresholdPos trigger for the reference trigger, use the `ReferenceTrigger.SupportsPosThresholdTrigger` property. If this property returns a value of True, a ThresholdPos trigger is supported.

To determine which channels support a threshold trigger for the start trigger, use the `Trigger.SupportedThresholdTriggerChannels` property. To set the channel that you want to use for the threshold start trigger, use the `Trigger.ThresholdTriggerChannel` property.

To determine which channels support a threshold trigger for the reference trigger, use the `ReferenceTrigger.SupportedThresholdTriggerChannels` property. To set the channel that you want to use for the threshold reference trigger, use the `ReferenceTrigger.ThresholdTriggerChannel` property.

On some devices, the threshold level is set using an analog output subsystem on the device. On other devices, you set the threshold level using the `Trigger.Level` property (for the start trigger) or `ReferenceTrigger.Level` property (for the reference trigger). By default, the trigger threshold value is in voltage unless specified otherwise for the device; see the user’s manual for your device for valid threshold value settings.
Note: The threshold level set by the Trigger.Level or ReferenceTrigger.Level property depends on the voltage range and gain of the subsystem. For example, if the voltage range of the analog input subsystem is ±10 V, and the specified gain is 1, specify a threshold voltage level within ±10 V. Likewise, if the voltage range of the analog input subsystem is ±10 V, and the specified gain is 10, specify a threshold voltage level within ±1 V. Refer to your device documentation for details on how to specify the threshold value for your device.

**ThresholdNeg Trigger Source**

A threshold trigger is generally either an analog signal from an analog input channel or an external analog signal attached to the device. A negative analog threshold trigger (ThresholdNeg) occurs when the device detects a negative-going signal that crosses a threshold value.

To determine if the subsystem supports a ThresholdNeg trigger for the start trigger, use the Trigger.SupportsNegThresholdTrigger property. If this property returns a value of True, a ThresholdNeg trigger is supported.

To determine if the subsystem supports a ThresholdNeg trigger for the reference trigger, use the ReferenceTrigger.SupportsNegThresholdTrigger property. If this property returns a value of True, a ThresholdNeg trigger is supported.

To determine which channels support a threshold trigger for the start trigger, use the Trigger.SupportedThresholdTriggerChannels property. To set the channel that you want to use for the threshold start trigger, use the Trigger.ThresholdTriggerChannel property.

To determine which channels support a threshold trigger for the reference trigger, use the ReferenceTrigger.SupportedThresholdTriggerChannels property. To set the channel that you want to use for the threshold reference trigger, use the ReferenceTrigger.ThresholdTriggerChannel property.

On some devices, the threshold level is set using an analog output subsystem on the device. On other devices, you set the threshold level using the Trigger.Level property (for the start trigger) or the ReferenceTrigger.Level property (for the reference trigger). By default, the trigger threshold value is in voltage unless specified otherwise for the device; see the user’s manual for your device for valid threshold value settings.

Note: The threshold level set by the Trigger.Level or ReferenceTrigger.Level property depends on the voltage range and gain of the subsystem. For example, if the voltage range of the analog input subsystem is ±10 V, and the specified gain is 1, specify a threshold voltage level within ±10 V. Likewise, if the voltage range of the analog input subsystem is ±10 V, and the specified gain is 10, specify a threshold voltage level within ±1 V. Refer to your device documentation for details on how to specify the threshold value for your device.
DigitalEvent Trigger Source

For a DigitalEvent trigger source, a trigger is generated when an external digital event occurs.

To determine if the subsystem supports a DigitalEvent trigger for the start trigger, use the `Trigger.SupportsDigitalEventTrigger` property. If this property returns a value of True, a DigitalEvent trigger is supported.

To determine if the subsystem supports a DigitalEvent trigger for the reference trigger, use the `ReferenceTrigger.SupportsDigitalEventTrigger` property. If this property returns a value of True, a DigitalEvent trigger is supported.

Setting up a Post-Trigger Scan Count

On devices that support a reference trigger for performing continuous pre- and post-trigger analog input operations, you can specify how many samples to acquire after the reference trigger occurs using the `AnalogInputSubsystem.ReferenceTrigger.PostTriggerScanCount` property.

To determine if your device supports the ability to specify the number of post-trigger samples to acquire, use the `AnalogInputSubsystem.ReferenceTrigger.SupportsPostTriggerScanCount` property.

Setting up Buffers

Note: Single-value operations do not use buffers.

Continuous analog input and analog output operations require buffers in which to store data. For input operations, a queue exists to hold the buffers that are empty and ready for input. For output operations, the queue holds buffers that you have filled with data and are ready for output.

To determine if the subsystem supports buffering, use the `SupportsBuffering` property within the appropriate subsystem class. If this property returns a value of True, buffering is supported.

If you want to acquire one buffer of data from one channel using a continuous analog input operation, use the `AnalogInputSubsystem.GetOneBuffer` method; this method allocates an `OlBuffer` object of the size you specify and acquires one buffer of data for you.

For all other operations, use the `OlBuffer` constructor within the `OlBuffer` class to create an `OlBuffer` object for use with an analog input or analog output subsystem. The library automatically allocates an internal data buffer, which is encapsulated by the `OlBuffer` object. You specify the subsystem with which to associate the `OlBuffer` object as well the size (in samples) of the internal buffer to allocate.
If desired, you can use the `OlBuffer.Tag` property, if desired, to name the buffer with the contents that are contained in the buffer.

**Note:** If you set the size of the internal buffer that is encapsulated by an OlBuffer object and later you want to change the size, call the `OlBuffer.Reallocate` method. This method reallocates the internal buffer to the specified number of samples; the initial internal buffer is deallocated and any data that it contained is lost.

The `AnalogInputSubsystem.GetOneBuffer` method uses one buffer. Other continuous analog input operations require a minimum of two OlBuffer objects. Continuous analog output operations require a minimum of two OlBuffer objects if `WrapSingleBuffer` is False; if `WrapSingleBuffer` is True, one OlBuffer object is required.

Once you have created the OlBuffer objects for multiple buffer operations (and, for output operations, filled the corresponding internal buffers with data), put the OlBuffer objects on the queue using the `BufferQueue.QueueBuffer` method of the appropriate subsystem.

The following example shows how to create multiple OlBuffer objects for a continuous analog input operation and put them on the queue for the analog input subsystem. In this example, an internal buffer of 1024 samples is allocated when the OlBuffer object is created:

**Visual C#**

```csharp
// Create the buffers
for (int i=0; i<4; ++i)
{
    AinBuffer[i] = new OlBuffer (1024, ainSS);
    // Put the buffers on the queue
    ainSS.BufferQueue.QueueBuffer (AinBuffer[i]);
}
```

**Visual Basic**

```vbnet
While i < 4
    ' Create the buffers
    AinBuffers(i) = New OlBuffer(1024, ainSS)
    ' Put the buffers on the queue
    ainSS.BufferQueue.QueueBuffer(AinBuffers(i))
    i += 1
End While
```

When you start a continuous operation, the device takes up to eight OlBuffer objects from the subsystem queue and begins filling them (for input operations) or outputting data from them (for output operations) at the specified clock rate. The state of these objects changes from queued to inprocess.
About QueuedCount and InProcessCount

You can determine the number of OlBuffer objects that are on the subsystem queue by using the `BufferQueue.QueuedCount` property. You can determine the number of OlBuffer objects that are in process by using the `BufferQueue.InProcessCount` property.

Every time an OlBuffer object transitions from the queued state to the in process state, the value of the `QueuedCount` property decreases by 1 and the value of the `InProcessCount` property increases by 1. For example, assume that you call `QueueBuffer` for 10 OlBuffer objects; the `QueuedCount` is 10 and the `InProcessCount` is 0. Once you call `Start` for the subsystem, up to 8 OlBuffer objects are moved from the queued state to the in process state. `QueuedCount` is now 2 and `InProcessCount` is 8.

If you do not put the OlBuffer objects back on the queue as they are completed, the `QueuedCount` decreases while the `InProcessCount` remains the same (as a new inprocess buffer replaces a completed buffer) until the `QueuedCount` gets to 0, then the `InProcessCount` starts decreasing until all the OlBuffer objects are completed, as shown below:

Buffer Completion Events

Note: Buffer completion events are not generated if you use the AnalogInputSubsystem.GetOneBuffer method. This is a synchronous method that does not return until the buffer has been acquired or the timeout value has expired.

One or more of the following events is generated when a buffer is completed:

- **BufferDoneEvent** – For input operations, this event is generated when the internal buffer of the OlBuffer object has been filled with post-trigger data. For output operations, this event is generated when all the data in the internal buffer of the OlBuffer object has been output. Refer to page 334 for more information on this event.

- **PreTriggerBufferDoneEvent** – For input operations only, this event is generated when the internal buffer of the OlBuffer object has been filled with pre-trigger data. Refer to page 336 for more information on this event.

- **QueueStoppedEvent** – This event occurs when you stop a continuous analog I/O operation with Stop or Abort. Refer to page 337 for more information on this event.

- **IOCompleteEvent** – For analog input operations that use a reference trigger whose trigger type is something other than software (none), this event occurs when the last post-trigger sample is copied into the user buffer; devices that do not support a reference trigger will never receive this event for analog input operations. For analog output operations, this event is generated when the last data point has been output from the analog output channel. Refer to page 338 for more information on this event.

- **QueueDoneEvent** – This event is generated when no OlBuffer objects are available on the queue and the operation stops. Refer to page 340 for more information on this event.

Handling Input Buffers

Each time a BufferDoneEvent or PreTriggerBufferDoneEvent event is raised, your application program must handle the event or you will lose the data in the internal buffer of the OlBuffer object. Refer to page 332 for more information about handling events and buffers.

You can post-process OlBuffer objects, if you wish. One technique for doing this is to allocate an array that will hold the OlBuffer objects as they are completed. When the BufferDoneEvent or PreTriggerBufferDoneEvent event occurs, move the OlBuffer object into a array. When the operation is complete, process the OlBuffer objects in your array.

For continuous analog input operations, use one of the following methods to copy the data from the internal buffer of an OlBuffer object into a user-declared array/variable (the data type of this array/variable is dictated by the method/property you choose):

Note: For ease of use, all of these methods allocate the returned array to the correct size. Simply declare an array of the appropriate type for use with one these methods.
• **OlBuffer.GetDataAsRawByte** – Copies the data, as raw counts, from the internal buffer of the OlBuffer object into a user-declared array of bytes. You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

To use this method, first declare an array of bytes.

---

**Note:** This method is useful when writing binary data to a file. Since each sample takes more than one array entry, other uses may be limited.

---

• **OlBuffer.GetDataAsRawInt16** – Used when the resolution of the subsystem is 16 bits or less and when the data encoding is twos complement, copies the data, as raw counts, from the internal buffer of the OlBuffer object into a user-declared array of signed, 16-bit integers (short). You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

To use this method, first declare an array of signed, 16-bit integers (short).

• **OlBuffer.GetDataAsRawUInt16** – Used when the resolution of the subsystem is 16 bits or less and when the data encoding is binary, copies the data, as raw counts, from the internal buffer of the OlBuffer object into a user-declared array of unsigned, 16-bit integers (ushort). You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

To use this method, first declare an array of unsigned, 16-bit integers (ushort).

• **OlBuffer.GetDataAsRawUInt32** – Used when the resolution of the subsystem is greater than 16 bits, copies the data, as raw counts, from the internal buffer of the OlBuffer object into a user-declared array of unsigned 32-bit integers (uint). You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

To use this method, first declare an array of unsigned, 32-bit integers (uint).

• **OlBuffer.GetDataAsSensor** – Converts the data from the internal buffer of the OlBuffer object into sensor values using the specified sensor gain and offset (described on page 289), and copies this data into a user-declared array of 64-bit floating-point values (double). You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

To use this method, first declare an array of 64-bit floating-point (double) values.

• **OlBuffer.GetDataAsVolts** – Converts the data from the internal buffer of the OlBuffer object into voltages, and copies this data into a user-declared array of 64-bit floating-point (double) values. You can copy all the data from the buffer or only the data for a specific ChannelListEntry in the buffer. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

To use this method, first declare an array of 64-bit floating-point (double) values.
• **OlBuffer.GetDataAsVoltsByte** – For a specified ChannelListEntry, converts the data from the internal buffer of an OlBuffer object into voltage values, and then copies these voltage values into a user-declared array of bytes. Each temperature value is stored as an Int32, and takes 4 bytes.

To use this method, first declare an array of bytes.

• **OlBuffer.GetDataAsRpm** – For a specified ChannelListEntry, converts the tachometer data from the internal buffer of an OlBuffer object into RPM (rotations per minute) values, and then copies these values into a user-declared array of 64-bit floating-point (double) values. Note that if the ChannelListEntry occurs more than once in the buffer, the data for each occurrence of the ChannelListEntry is copied.

To use this method, first declare an array of 64-bit floating-point (double) values.

• **OlBuffer.Item** property ([]) – Copies the raw count value at the specified index of the buffer specified by the OlBuffer object into a user-declared signed, 32-bit integer variable (int).

When you have finished copying the data from the internal buffer of the OlBuffer object, you can put the OlBuffer object back on the queue for the analog input subsystem using the AnalogInputSubsystem.BufferQueue.QueueBuffer method.

See the example for the event BufferDoneEvent starting on page 334 for an example of using the GetDataAsSensor method to handle input buffers.

### Handling Output Buffers

For continuous analog output operations, you need to create an array and fill it with data, then copy this data from the array to the internal buffer of the OlBuffer object using one of the following methods:

• **OlBuffer.PutDataAsRaw** – Copies raw counts from a user-specified array into the internal buffer of the OlBuffer object. This is an overloaded method that allows you to copy all the data from the array into the buffer or only the data for a specific ChannelListEntry in the array into the buffer. Note that if the ChannelListEntry occurs more than once in the array, the data for each occurrence of the ChannelListEntry is copied.

If your subsystem supports a resolution of 16-bits or less, declare an array of unsigned, 16-bit integers (ushort) for use with this method.

If your subsystem supports a resolution greater than 16 bits, declare an array of unsigned, 32-bit integers (uint) for use with this method.

• **OlBuffer.PutDataAsVolts** – Copies voltages from a user-specified array into the internal buffer of the OlBuffer object. This is an overloaded method that allows you to copy all the data from the array into the buffer or only the data for a specific ChannelListEntry in the array into the buffer. Note that if the ChannelListEntry occurs more than once in the array, the data for each occurrence of the ChannelListEntry is copied.

Declare an array of 64-bit floating-point values (double) for use with this method.

When you have finished copying the data into the internal buffer of the OlBuffer object, put the OlBuffer object back on the queue for the analog output subsystem using the AnalogOutputSubsystem.BufferQueue.QueueBuffer method.
The following example shows how to create an OlBuffer object, fill the internal buffer of this OlBuffer object with 100 samples, and put the OlBuffer object on the analog output subsystem queue:

**Visual C#**

```csharp
// Allocate a buffer of 100 samples
DacBuffer = new OlBuffer(100, aoutSS);
// Create an array of data
for (int i = 0; i < 100; i++)
{
    data[i] = i;
}
// Copy the raw data to the buffer
DacBuffer.PutDataAsRaw(data);
// Queue the buffer for output
aoutSS.BufferQueue.QueueBuffer(DacBuffer);
```

**Visual Basic**

```vbnet
' Allocate a buffer of 100 samples
DacBuffer = New OlBuffer(100, aoutSS)
' Create an array of data
Dim i As Integer
For i = 0 To 99
    data(i) = i
Next i
' Copy the raw data to the buffer
DacBuffer.PutDataAsRaw(data)
' Queue the buffer for output
aoutSS.BufferQueue.QueueBuffer(DacBuffer)
```

### Getting Information about a Buffer

The DT-Open Layers for .NET Class Library provides the following additional properties for getting information about buffers:

- **OlBuffer.BufferSizeInBytes** – Returns the size, in bytes, of the internal data buffer that is encapsulated by the OlBuffer object.
- **OlBuffer.BufferSizeInSamples** – Returns the size, in samples, of the internal data buffer that is encapsulated by the OlBuffer object.
- **OlBuffer.ChannelListOffset** – Returns the index into the ChannelList that corresponds to the first sample in the internal buffer of the OlBuffer object.
- **OlBuffer.Encoding** – Returns the data encoding for the raw data (binary or twos complement) in the internal buffer of the OlBuffer object.
- **OlBuffer.RawDataFormat** – Returns the format of the raw data (Int16, Uint16, Int32, Float (32-bit float), or Double (64-bit float)) in the internal buffer of the OlBuffer object.
- **OlBuffer.Resolution** – Returns the resolution of the subsystem that is associated with the OlBuffer object.
- **OlBuffer.SampleSizeInBytes** – Returns the size of a sample, in bytes. Typically, each sample requires 2 bytes.
• **OlBuffer.State** property – Returns the state of the OlBuffer object. Valid states are as follows:
  
  - **Idle** – The OlBuffer object has been created, but has not been queued to a subsystem.
  - **Queued** – The OlBuffer object has been queued to a subsystem with `OlBuffer.QueueBuffer`.
  - **InProcess** – The OlBuffer object has been sent to the device driver for processing. A maximum of eight OlBuffer objects can be in process at one time.
  - **Completed** – For an input operation, the internal buffer of the OlBuffer object has been filled, and the OlBuffer object has not been put back on queue for the subsystem. For an output operation, all the data in the internal buffer of the OlBuffer object has been output, and the OlBuffer object has not been put back on the queue for the subsystem.
  - **Released** – The internal data buffer of the OlBuffer object has been deallocated by calling `OlBuffer.Dispose`.

• **OlBuffer.ValidSamples** – Returns the number of valid samples in the internal buffer of the OlBuffer object.

  For analog input operations, the `ValidSamples` property is set to the number of samples in the completed buffer under normal circumstances. However, in some cases, like if **Abort** is called in the middle of an operation, `ValidSamples` reflects the number of samples in the buffer when **Abort** was called. In addition, if **Abort** or **Stop** is called, any OlBuffer object whose state is Inprocess will have a **ValidSamples** of 0.

  For analog output operations, **ValidSamples** is always equal to the maximum number of samples that the buffer was allocated to hold.

• **OlBuffer.VoltageRange** – Returns the upper limit and lower limit of the voltage range for the associated subsystem.

### Cleaning up Buffers

When you are finished performing continuous analog I/O operations, use can use one of the following methods to clean up the OlBuffer objects:

• **BufferQueue.DequeueBuffer** – Removes and returns the OlBuffer object at the front of the queue.

• **BufferQueue.FreeAllQueuedBuffers** – Removes all OlBuffer objects from the queue and deallocates the internal data buffers that are encapsulated by them.
Starting Subsystems Simultaneously

If supported, you can set up subsystems to start simultaneously. Note that you cannot perform simultaneous startup on subsystems configured for single-value operations unless you are using a simultaneous sampling module.

To determine if a subsystem supports simultaneous start, use the SupportsSimultaneousStart property inherited from the SubsystemBase class. If this property returns a value of True, the subsystem can be simultaneously started.

You can synchronize the triggers of subsystems by specifying the same trigger source for each of the subsystems that you want to start simultaneously; ensure that the triggers are wired appropriately to the device.

Use the SimultaneousStart.AddSubsystem method to add the subsystems that you want to start simultaneously to the start list. If, later, you want to remove a subsystem from the start list, use the SimultaneousStart.RemoveSubsystem method.

To return an array of subsystems that were added to the simultaneous start list, use the SimultaneousStart.GetSubsystemList method.

Pre-start the subsystems using the SimultaneousStart.PreStart method. Pre-starting a subsystem ensures a minimal delay once the subsystems are started. Once you call the SimultaneousStart.PreStart method, do not alter the settings of the subsystems on the simultaneous start list.

Start the subsystems using the SimultaneousStart.Start method. When started, both subsystems are triggered simultaneously.

When you are finished with the operations, call the SimultaneousStart.Clear method to remove the subsystems from the simultaneous start list.
Auto-Calibrating a Subsystem

Some devices provide a self-calibrating feature, where a specified subsystem performs an auto-zero function. To determine if the specified subsystem supports this capability, use the `AnalogInputSubsystem.SupportsAutoCalibrate` property. If this property returns a value of `True`, the subsystem can be calibrated through software.

To calibrate the subsystem in software, call the `AutoCalibrate` method. Ensure that the subsystem is not running when you call this method, or an error is returned.
Handling Events

DT-Open Layers devices notify your application of buffer movement and other system activities by raising events.

Delegates, which behave like function pointers, are provided to handle these events. Each delegate has a specific signature and holds a reference to a method that matches its signature. When an event occurs, the appropriate method (with the matching signature) is called.

The following example shows the declaration for the BufferDoneHandler delegate provided by the DT-Open Layers for .NET Class Library:

[C#]

```csharp
public delegate void BufferDoneHandler(object sender, BufferDoneEventArgs eventArgs);
```

[Visual Basic]

```
Public Delegate Sub BufferDoneHandler(sender As Object, eventArgs As BufferDoneEventArgs)
```

As you can see, the syntax of the delegate is similar to that of a method declaration; however, the delegate keyword informs the compiler that BufferDoneHandler is a delegate type. By convention, event delegates in the .NET Framework have two parameters, the source that raised the event and the data for the event.

To handle events, you must define a method that matches the delegate; this is the event handling method that is called when the appropriate event is raised. In the following example, the event handling method called MyBufferDone matches the signature of the BufferDoneHandler delegate and is called when the event BufferDoneEvent is raised:

[Visual C#]

```
public void MyBufferDone (object sender, BufferDoneEventArgs eventArgs);
```
Visual Basic

' MyBufferDone has the same signature as BufferDoneHandler.
Public Sub MyBufferDone(sender As Object,
    eventArgs As BufferDoneEventArgs)
' Add you own code here
End Sub

Note: To ensure that events are handled in the main application, use the InvokeRequired method. Refer to your .NET documentation for more information on this method.

Lastly, you must associate the event and event handling method with the appropriate subsystem. The following example shows how to associate the event BufferDoneEvent and the MyBufferDoneHandler event handler to the analog input subsystem called ainSS:

Visual C#

// Associate the event BufferDoneEvent and the event handling method
// MyBufferDone with the analog input subsystem ainSS.
ainSS.BufferDoneEvent += new BufferDoneHandler (MyBufferDoneHandler);

Note: In C#, when you want to disable receiving events, use the -= operator instead of the += operator. See your .NET documentation for more information about events and delegates.

Visual Basic

' Associate the event BufferDoneEvent and the event handling method
' MyBufferDone with the analog input subsystem ainSS.
AddHandler ainSS.BufferDoneEvent, Address of MyBufferDoneHandler

Note: In Visual Basic, when you want to disable receiving events, use the RemoveHandler statement instead of the AddHandler statement. See your .NET documentation for more information about events and delegates.

The following subsections describe the events and delegates that are provided in the DT-OpenLayers for .NET Class Library. Refer to the examples provided with this software package to see how to incorporate event handling code into your program.
**BufferDoneEvent**

For input operations, the event BufferDoneEvent is raised when the internal data buffer of the OlBuffer object has been filled with post-trigger data. For output operations, this event is raised when all the data in the internal data buffer of the OlBuffer object has been output.

If you stop an analog I/O operation, the event BufferDoneEvent is generated for the current OlBuffer object and for up to eight inprocess OlBuffer objects before a QueueStoppedEvent event occurs.

Use the `BufferDoneHandler` delegate with BufferDoneEvent. When BufferDoneEvent is raised, the subsystem that raised the event, the time stamp of when the event occurred, and the completed OlBuffer object are passed in the BufferDoneEventArgs argument of the user-defined method that matches the signature of the `BufferDoneHandler` delegate.

You can add your own code to the event handling method to manage the data in the buffer or perform other operations as required by your application. Refer to page 325 for more information on handling input buffers; refer to page 327 for more information on handling output buffers.

**Note:** If your program is running under a heavy CPU load, and if the `AnalogInputSubsystem.SynchronousBufferDone` property is set to False (the default condition), .NET may call your BufferDoneEvent delegates out of order under some circumstances. To avoid this problem, it is recommended that you set the `AnalogInputSubsystem.SynchronousBufferDone` property to True, so that all BufferDoneEvent events are executed synchronously in a single worker thread instead of asynchronously using a separate thread for each event.

The following is an example of an event handling routine called HandleBufferDone that handles the event BufferDoneEvent. This event handler converts the data from the internal buffer of the OlBuffer object into sensor values and copies the data into a user-dimensional array called `buf`. The first 10 samples are printed to the form, and the OlBuffer object is put back on the queue for the subsystem:

**Visual C#**

```csharp
public void HandleBufferDone (object sender, BufferDoneEventArgs bufferDoneData)
{
    if (this.InvokeRequired)
    {
        this.Invoke( new BufferDoneHandler (HandleBufferDone),
                    new object[] {sender, bufferDoneData });
    }
}
```
else
{
    // Get the data as sensor values
    double[] buf = olBuffer.GetDataAsSensor();
    // requeue the completed buffer
    ainSS.BufferQueue.QueueBuffer (olBuffer);
    // Output the first 10 samples to the user form
    for (int i=0; i<10; ++i)
    {
        OlBufferDataTable.Rows[i][0] = buf[i];
    }
}

Visual Basic
Public Sub HandleBufferDone(ByVal sender As Object,
                             ByVal bufferDoneData As BufferDoneEventArgs)
    If Me.InvokeRequired Then
        Me.Invoke(New BufferDoneHandler(
            AddressOf HandleBufferDone), New Object()
            {sender, bufferDoneData})
    Else
        ' Get the data as sensor values
        Dim buf As Double() = olBuffer.GetDataAsSensor()
        ' requeue the completed buffer
        ainSS.BufferQueue.QueueBuffer(olBuffer)
    End If
    ' Output the first 10 samples to the user form
    Dim i As Integer
    While i < 10
        OlBufferDataTable.Rows{i}{0} = buf{i}
        i += 1
    End While
End Sub 'HandleBufferDone
PreTriggerBufferDoneEvent

The event PreTriggerBufferDone is raised when the internal buffer of the OlBuffer object is filled with pre-trigger data (for an input operation only). Refer to page 322 for more information about buffers.

Use the PreTriggerBufferDoneHandler delegate with PreTriggerBufferDoneEvent. When PreTriggerBufferDoneEvent is raised, the subsystem that raised the event, the time stamp of when the event occurred, and the completed OlBuffer object are passed in the BufferDoneEventArgs argument of the user-defined method that matches the signature of the PreTriggerBufferDoneHandler delegate.

You can add your own code to the event handling method to manage the data in the buffer or perform other operations as required by your application. Refer to page 325 for more information on handling input buffers.

The following is an example of an event handling routine called HandlePreTriggerBufferDone that handles the event PreTriggerBufferDoneEvent. This event handler converts the data from the internal buffer of the OlBuffer object into voltage values and copies the data into a user-dimensioned array called buf. The first 10 samples are printed to the form, and the OlBuffer object is put back on the queue for the subsystem:

Visual C#

```csharp
public void HandlePreTriggerBufferDone (object sender, BufferDoneEventArgs bufferDoneData)
{
    if (this.InvokeRequired)
    {
        this.Invoke( new PreTriggerBufferDoneHandler (HandlePreTriggerBufferDone), new object[] { sender, bufferDoneData});
    }
    else
    {
        // Get the data as voltages
        double[] buf = olBuffer.GetDataAsVolts();

        // requeue the completed buffer
        ainSS.BufferQueue.QueueBuffer (olBuffer);

        // Output the first 10 samples to the user form
        for (int i=0; i<10; ++i)
        {
            OlBufferDataTable.Rows[i][0] = buf[i];
        }
    }
}
```
Visual Basic

Public Sub HandlePreTriggerBufferDone(ByVal sender As Object, ByVal bufferDoneData As BufferDoneEventArgs)
    If Me.InvokeRequired Then
        Me.Invoke(New PreTriggerBufferDoneHandler(AddressOf HandlePreTriggerBufferDone), New Object() {sender, bufferDoneData})
    Else
        ' Get the data as voltages
        Dim buf As Double() = olBuffer.GetDataAsVolts()
        ' requeue the completed buffer
        ainSS.BufferQueue.QueueBuffer(olBuffer)
    End If
    ' Output the first 10 samples to the user form
    Dim i As Integer
    While i < 10
        OlBufferDataTable.Rows(i)(0) = buf(i)
        i += 1
    End While
End Sub 'HandleBufferDone

QueueStoppedEvent

A QueueStoppedEvent is raised when Stop or Abort is called for a continuous analog input or analog output operation.

Note: The event BufferDoneEvent is generated for the current OlBuffer object and for up to eight inprocess OlBuffer objects before a QueueStoppedEvent event occurs.

Use the QueueStoppedHandler delegate with QueueStoppedEvent. When QueueStoppedEvent is raised, the subsystem that raised the event and the time stamp of when the event occurred are passed in the GeneralEventArgs argument of the user-defined method that matches the signature of the QueueStoppedHandler delegate.

The following is an example of an event handling routine called HandleQueueStopped that handles the event QueueStoppedEvent. This event handler displays a message on the form that indicates which subsystem raised the QueueStoppedEvent and at what time the event occurred:
Visual C#

```csharp
public void HandleQueueStopped (object sender,
    GeneralEventArgs eventData)
{
    if (this.InvokeRequired)
    {
        this.Invoke(new QueueStoppedHandler(HandleQueueStopped)
            ,new object[] { sender, eventData });
    }
    else
    {
        string msg = String.Format ("Queue Stopped received on
            subsystem {0} element {1} at time {2}",
            eventData.Subsystem, eventData.Subsystem.Element,
            eventData.DateTime.ToString("T"));

        statusBarPanel.Text = msg;
    }
}
```

Visual Basic

```vbnet
Public Sub HandleQueueStopped(ByVal sender As Object,
    ByVal eventData As GeneralEventArgs)
    If Me.InvokeRequired Then
        Me.Invoke(New QueueStoppedHandler(
            AddressOf HandleQueueStopped),
            New Object() {sender, eventData})
    Else
        Dim msg As String = String.Format(
            "Queue Stopped received on subsystem {0} element {1} at time {2}",
            eventData.Subsystem, eventData.Subsystem.Element,
            eventData.DateTime.ToString("T"))

        statusBarPanel.Text = msg
    End If
End Sub 'HandleQueueStopped
```

**IOCompleteEvent**

For analog input operations that use a reference trigger whose trigger type is something other than software (none), the event IOCompleteEvent is raised when the last post-trigger sample is copied into the user buffer. This event includes the total number of samples per channel that were acquired from the time acquisition was started (with the start trigger) to the last post-trigger sample. For example, a value of 100 indicates that a total of 100 samples (samples 0 to 99) were acquired. In some cases, this message is generated well before the events BufferDoneEvent are generated. You can determine when the reference trigger occurred and the number of pre-trigger samples that were acquired by subtracting the post trigger scan count, described on page 322, from the total number of samples that were acquired. Devices that do not support a reference trigger will never receive this event for analog input operations.
For analog output operations, the event IOCompleteEvent is raised when the last data point has been output from an analog output channel. In some cases, this event is raised well after the data is transferred from the buffer (and, therefore, well after BufferDoneEvent and QueueDoneEvents are raised). Refer to page 322 for more information on buffers.

Use the **IOCompleteHandler** delegate with IOCompleteEvent. When IOCompleteEvent is raised, the subsystem that raised the event and the time stamp of when the event occurred are passed in the IOCompleteEventsArgs argument of the user-defined method that matches the signature of the **IOCompleteHandler** delegate.

You can add your own code to the event handling method to deal with this event as needed.

The following is an example of an event handling routine called HandleIOComplete that handles the event IOCompleteEvent. This event handler displays a message on the form that indicates which subsystem raised the IOCompleteEvent and at what time the event occurred:

**Visual C#**

```csharp
public void HandleIOComplete (object sender,
   IOCompleteEventArgs eventData)
{
   if (this.InvokeRequired)
   {
      this.Invoke( new IOCompleteHandler (HandleIOComplete),
      new object[] {sender, eventData });
   }

   else
   {
      string msg = String.Format("IOComplete received on
   subsystem {0} at time {1}", eventData.Subsystem,
   eventData.DateTime.ToString("T");
      statusBarPanel.Text = msg;
   }
}
```

**Visual Basic**

```vbnet
Public Sub HandleIOComplete(ByVal sender As Object,
   ByVal eventData As IOCompleteEventArgs)
If Me.InvokeRequired Then
   Me.Invoke(New IOCompleteHandler(
      AddressOf HandleIOComplete),
   New Object() {sender, eventData})
Else
   Dim msg As String = String.Format("IOComplete received on subsystem {0} at time {1}",
   eventData.Subsystem, eventData.DateTime.ToString("T");
      statusBarPanel.Text = msg
End If
End Sub 'HandleIOComplete
```
QueueDoneEvent

The event QueueDoneEvent is raised when no OlBuffer objects are available on the queue and the operation stops. Refer to page 322 for more information.

Use the QueueDoneHandler delegate with QueueDoneEvent. When QueueDoneEvent is raised, the subsystem that generated the event and the time stamp of when the event occurred are passed in the GeneralEventArgs argument of the user-defined method that matches the signature of the QueueDoneHandler delegate.

The following is an example of an event handling routine called HandleQueueDone that handles the event QueueDoneEvent. This event handler displays a message on the form that indicates which subsystem raised the QueueDoneEvent and at what time the event occurred:

**Visual C#**

```csharp
public void HandleQueueDone (object sender,
     GeneralEventArgs eventData)
{
    if (this.InvokeRequired)
    {
        this.Invoke(new QueueDoneHandler(HandleQueueDone),
            new object[] { sender, eventData });
    }
    else
    {
        string msg = String.Format (
            "Queue Done received on {0} element {1} at time {2}",
            eventData.Subsystem,
            eventData.Subsystem.Element,
            eventData.DateTime.ToString("T"));
        statusBarPanel.Text = msg;
    }
}
```

**Visual Basic**

```vbnet
Public Sub HandleQueueDone(ByVal sender As Object,
     ByVal eventData As GeneralEventArgs)
    If Me.InvokeRequired Then
        Me.Invoke(New QueueDoneHandler(AddressOf HandleQueueDone),
            New Object() {sender, eventData})
    Else
        Dim msg As String = String.Format(
            "Queue Done received on {0} element {1} at time {2}",
            eventData.Subsystem, eventData.Subsystem.Element,
            eventData.DateTime.ToString("T"))
        statusBarPanel.Text = msg
    End If
End Sub 'HandleQueueDone
```
DriverRunTimeErrorEvent

The DriverRunTimeErrorEvent occurs when the device driver detects one of the following error conditions:

- **FifoOverflow** – The driver could not read data from the device FIFO (or Windows USB FIFO) fast enough, resulting in a FIFO overflow condition. To deal with this error, increase the size of the buffers, slow down the sampling rate, or stop other CPU-intensive running programs.

  **Note:** By setting the `AnalogInputSubsystem.StopOnError` property, you can determine how the subsystem operates if an overrun occurs. If `StopOnError` is True, the subsystem will automatically stop when an overrun is detected. If `StopOnError` is False, the subsystem will continue running if an overrun is detected.

- **FifoUnderflow** – The driver could not write data to the device FIFO (or Windows USB FIFO) fast enough, resulting in FIFO underflow condition. To deal with this error, increase the size of buffers, slow down the sampling rate, or stop other CPU-intensive running programs.

  **Note:** By setting the `AnalogOutputSubsystem.StopOnError` property, you can determine how the subsystem operates if an underrun occurs. If `StopOnError` is True, the subsystem will automatically stop when an underrun is detected. If `StopOnError` is False, the subsystem will continue running if an underrun is detected.

- **DeviceOverClocked** – The A/D clock (usually external clock) is running too fast on the device. To deal with this error, slow down the A/D clock.

- **TriggerError** – The driver detected a trigger on the device but did not act on it.

- **DeviceError** – Generated by the driver due to a USB bus or hardware problem. To deal with this error, stop connecting/disconnecting USB devices while streaming data to them.

Use the `DriverRunTimeErrorEventHandler` delegate with `DriverRunTimeErrorEvent`. When `DriverRunTimeErrorEvent` is raised, the subsystem that generated the event, the time stamp of when the event occurred, the error code, and the error code descriptor are passed in the `DriverRunTimeErrorEventArgs` argument of the user-defined method that matches the signature of the `DriverRunTimeErrorEventHandler` delegate.

The following is an example of an event handling routine called `HandleDriverRunTimeErrorEvent` that handles the event `DriverRunTimeErrorEvent`. This event handler displays a message on the form that indicates what error occurred, which subsystem raised the `DriverRunTimeErrorEvent`, and at what time the event occurred:
Visual C#

```csharp
public void HandleDriverRunTimeErrorEvent (object sender, 
DriverRunTimeErrorEventArgs eventData)
{
    if (this.InvokeRequired)
    {
        this.Invoke(new 
            DriverRunTimeErrorEventHandler(
                HandleDriverRunTimeErrorEvent),
            new object[] { sender, eventData });
    }
    else
    {
        string msg = String.Format( 
            "Error: {0} 
            Occurred on subsystem {1} element {2} at time {3}",
            eventData.Message, eventData.Subsystem,
            eventData.Subsystem.Element, 
            eventData.DateTime.ToString("T"));
        MessageBox.Show (msg, "Error");
    }
}
```

Visual Basic

```vbnet
Public Sub HandleDriverRunTimeErrorEvent(ByVal sender As Object, 
    ByVal eventData As DriverRunTimeErrorEventArgs)
    If Me.InvokeRequired Then
        Me.Invoke(New DriverRunTimeErrorEventHandler(
            AddressOf HandleDriverRunTimeErrorEvent),
            New Object() {sender, eventData})
    Else
        Dim msg As String = String.Format( 
            "Error: {0} Occurred on subsystem {1}
            element {2} at time {3}", eventData.Message, 
            eventData.Subsystem, eventData.Subsystem.Element, 
            eventData.DateTime.ToString("T"))
        MessageBox.Show(msg, "Error")
    End If
End Sub 'HandleDriverRunTimeErrorEvent
```

**GeneralFailureEvent**

The event GeneralFailureEvent is raised when a general library failure occurs.

Use the **GeneralFailureHandler** delegate with GeneralFailureEvent. When GeneralFailureEvent is raised, the subsystem that raised the event and the time stamp of when the event occurred are passed in the GeneralEventArgs argument of the user-defined method that matches the signature of the **GeneralFailureHandler** delegate.

You can add your own code to the handler to deal with this event as needed.
DeviceRemovedEvent

The event DeviceRemovedEvent is raised when a device is removed from your system while your application is running.

Use the `DeviceRemovedHandler` delegate with `DeviceRemovedEvent`. When `DeviceRemovedEvent` is raised, the subsystem that raised the event and the time stamp of when the event occurred are passed in the `GeneralEventArgs` argument of the user-defined method that matches the signature of the `DeviceRemovedHandler` delegate.

You can add your own code to the event handling method to deal with this event as needed.
Handling Errors

Errors are generated by the DT-Open Layers .NET Class Library as OlException objects. Each OlException object contains an OlError object, which contains the error code and its description. Your program should handle exceptions as they occur, performing the appropriate actions to deal with any errors that arise.

Refer to Appendix A for a list of error codes and messages. These values are defined as enumerations that are accessible using the OlException.ErrorCode and OlException.Message properties. If you want to determine which subsystem generated the error, use the OlException.Subsystem property.

The following example shows how to catch exceptions in your program; this example the error message is printed to text field on the form:

**Visual C#**

```csharp
catch (OlException ex)
{
    string err = ex.Message;
    statusBarPanel.Text = err;
    return;
}
```

**Visual Basic**

```vbnet
Catch ex As OlException
    Dim err As String = ex.Message
    statusBarPanel.Text = err
    Return
```

Cleaning Up Operations

When you are finished performing data acquisition operations, clean up the memory and resources that were used by the operation by doing the following:

1. Release the simultaneous start list, if used, using the SimultaneousStart.Clear method.
2. Deallocate any buffers, if used. Refer to page 329 for more information.
3. Release the subsystem connection to the device using the Dispose method within the appropriate subsystem class.

The flowcharts presented in the remainder of this chapter show how to perform typical input/output operations.

**Note:** Depending on your device, some of the settings may not be programmable. Refer to your device documentation for details.

Although the flowcharts do not show error checking, it is recommended that you add exception handling to your program.

Some steps represent several substeps; if you are unfamiliar with the detailed operations involved with any one step, refer to the indicated page for detailed information.
Single-Value Analog Input Operations

1. If you haven’t already done so, get an object of type DeviceMgr using the DeviceMgr.Get method.
2. If you haven’t already done so, get an object of type Device for the specified hardware device using the DeviceMgr.GetDevice method.
3. Get an object for each element of the subsystem that you want to use using the Device.AnalogInputSubsystem method.
4. Set the data flow mode to SingleValue using the AnalogInputSubsystem.DataFlow property.
5. Set up the analog input channel (see page 376).
6. Set up the common subsystem parameters (see page 382).
7. Configure the subsystem using the AnalogInputSubsystem.Config method.
8. Go to the next page.
Acquire a single value using one of the following methods:

- `AnalogInputSubsystem.GetSingleValueAsRaw` (for a raw count),
- `AnalogInputSubsystem.GetSingleValueAsVolts` (for a voltage value),
- `AnalogInputSubsystem.GetSingleValueAsSensor` (for a sensor value),
- `AnalogInputSubsystem.GetSingleValueAsTemperature` (for a temperature value),
- `AnalogInputSubsystem.GetSingleCjcValueAsTemperature` (for CJC temperature),
- `AnalogInputSubsystem.GetSingleValueAsResistance` (for a resistance value),
- `AnalogInputSubsystem.GetSingleValueAsCurrent` (for a current value),
- `AnalogInputSubsystem.GetSingleValueAsStrain` (for a microstrain value),
- `AnalogInputSubsystem.GetSingleValueAsBridgeBasedSensor` (for values in the native engineering units of the full-bridge-based sensors).

Acquire a single value from all input channels simultaneously using one of the following methods:

- `AnalogInputSubsystem.GetSingleValuesAsRaw` (for raw count values),
- `AnalogInputSubsystem.GetSingleValuesAsVolts` (for voltage values),
- `AnalogInputSubsystem.GetSingleValuesAsSensor` (for sensor values),
- `AnalogInputSubsystem.GetSingleValuesAsTemperature` (for temperature values),
- `AnalogInputSubsystem.GetSingleCjcValuesAsTemperature` (for CJC temperatures),
- `AnalogInputSubsystem.GetSingleValuesAsStrain` (for microstrain values), or
- `AnalogInputSubsystem.GetSingleValuesAsBridgeBasedSensor` (for values in the native engineering units of the full-bridge-based sensors).

When done with your program, clean up the subsystem (see page 398).
Single-Value Analog Output Operations

If you haven’t already done so, get an object of type DeviceMgr using the DeviceMgr.Get method.

If you haven’t already done so, get an object of type Device for the specified hardware device using the DeviceMgr.GetDevice method.

Get an object for each element of the subsystem that you want to use using the Device.AnalogOutputSubsystem method.

Set the data flow mode to SingleValue using the AnalogOutputSubsystem.DataFlow property.

Set the common subsystem parameters (see page 382).

Configure the subsystem using the AnalogOutputSubsystem.Config method.

Does subsystem support simultaneous output?

Output a single to each output channel using one of the following methods:

- AnalogOutputSubsystem.SetSingleValuesAsRaw (to output raw counts) or
- AnalogOutputSubsystem.SetSingleValuesAsVolts (to output voltages).

Output a single value using one of the following methods:

- AnalogOutputSubsystem.SetSingleValueAsRaw (to output a raw count) or
- AnalogOutputSubsystem.SetSingleValueAsVolts (to output a voltage).

Output another value?

When done with your program, clean up the subsystem (see page 398).
If you haven’t already done so, get an object of type DeviceMgr using the DeviceMgr.Get method.

If you haven’t already done so, get an object of type Device for the specified hardware device using the DeviceMgr.GetDevice method.

Get an object for each element of the subsystem that you want to use using the Device.DigitalInputSubsystem method.

Set the data flow mode to SingleValue using the DigitalInputSubsystem.DataFlow property.

Set the resolution of the subsystem using the DigitalInputSubsystem.Resolution property.

Configure the subsystem using the DigitalInputSubsystem.Config method.

Acquire another value?

Yes

No

When done with your program, clean up the subsystem (see page 398).
**Single-Value Digital Output Operations**

1. If you haven’t already done so, get an object of type `DeviceMgr` using the `DeviceMgr.Get` method.
2. If you haven’t already done so, get an object of type `Device` for the specified hardware device using the `DeviceMgr.GetDevice` method.
3. Get an object for each element of the subsystem that you want to use using the `Device.DigitalOutputSubsystem` method.
5. Set the resolution of the subsystem using the `DigitalOutputSubsystem.Resolution` property.
8. When done with your program, clean up the subsystem (see page 398).

Output another value?
- Yes
- No
Continuous Analog Input Operations - One Buffer

1. If you haven’t already done so, get an object of type DeviceMgr using the DeviceMgr.Get method.

2. If you haven’t already done so, get an object of type Device for the specified hardware device using the DeviceMgr.GetDevice method.

3. Get an object for the element of the analog input subsystem that you want to use using the Device.AnalogInputSubsystem method.

4. Use the AnalogInputSubsystem.DataFlow property to set the data flow mode to Continuous.

5. Set up the analog input channel (see page 376).

6. Add a single channel to the ChannelList (see page 380).

7. Set up common subsystem parameters (see page 382).

8. Set up the clocks (see page 383).

9. Set up the triggers (see page 384). Note that reference triggers are not supported for this operation type.

10. Configure the subsystem using the AnalogInputSubsystem.Config method.

11. Call the AnalogInputSubsystem.GetOneBuffer method to acquire one buffer of data from the specified analog input channel.

Go to the next page.
Copy the data from the internal buffer of an OlBuffer object to a user-specified array using

- `OlBuffer.GetDataAsRawByte` (converts to raw counts and copies into an array of bytes),
- `OlBuffer.GetDataAsRawInt16` (converts two's complement data into raw counts when the resolution is 16 bits or less and copies into an array of signed, 16-bit integers),
- `OlBuffer.GetDataAsRawUInt16` (converts binary data into raw counts when the resolution is 16 bits or less and copies into an array of unsigned 16-bit integers),
- `OlBuffer.GetDataAsRawUInt32` (converts to raw counts when the resolution is more than 16-bits and copies into an array of unsigned 32-bit integers),
- `OlBuffer.GetDataAsVolts` (converts to voltage and copies into an array of floating-point values),
- `OlBuffer.GetDataAsVoltsByte` (converts to voltage and copies into an array of bytes),
- `OlBuffer.GetDataAsSensor` (converts to sensor values and copies into an array of floating-point values),
- `OlBuffer.GetDataAsResistance` (converts to ohms and copies into an array of floating-point values),
- `OlBuffer.GetDataAsCurrent` (converts to amperes and copies into an array of floating-point values),
- `OlBuffer.GetDataAsTemperatureByte` (converts to temperature and copies into an array of bytes),
- `OlBuffer.GetDataAsTemperatureDouble` (converts to temperature and copies into an array of floating-point values),
- `OlBuffer.GetDataAsRpm` (converts to RPM values and copies into an array of floating-point values),
- `OlBuffer.GetDataAsStrain` (converts to microstrain values and copies into an array of floating-point values),
- `OlBuffer.GetDataAsBridgeBasedSensor` (converts to the engineering values of the full-bridge-based sensor and copies into an array of floating-point values), or
- `OlBuffer.GetDataAsNormalizedBridgeOutput` (converts to mV/Vexe and copies into an array of floating-point values).

When done with your program, clean up the subsystem (see page 398).
Continuous Analog Input Operations - Multiple Buffers

If you haven’t already done so, get an object of type DeviceMgr using the DeviceMgr.Get method.

If you haven’t already done so, get an object of type Device for the specified hardware device using the DeviceMgr.GetDevice method.

Get an object for the element of the analog input subsystem that you want to use using the Device.AnalogInputSubsystem method.

Use the AnalogInputSubsystem.DataFlow property to set one of the following data flow modes: Continuous for post-trigger operations, ContinuousPreTrigger for continuous pre-trigger operations, or ContinuousPrePostTrigger for continuous about-trigger operations.

Set up the analog input channels (see page 376).

Set up the ChannelList (see page 380).

Set up common subsystem parameters. (see page 382).

Set up the clocks (see page 383).

Set up the triggers (see page 384).

If you want to use triggered scan mode, set up the scan (see page 387.)

Set up buffering (see page 388).

Configure the subsystem using the AnalogInputSubsystem.Config method.

Go to the next page.
Continued from previous page.

Configure the subsystem to execute BufferDoneEvent events synchronously in a single thread using the `AnalogInputSubsystem.SynchronousBufferDone` property.

Start the operation with the `AnalogInputSubsystem.Start` method.

Deal with events and buffers (see page 390).

Stop the operation (see page 397).

When done with your program, clean up the subsystem (see page 398).
Continuous Analog Output Operations

1. If you haven’t already done so, get an object of type DeviceMgr using the DeviceMgr.Get method.
2. If you haven’t already done so, get an object of type Device for the specified hardware device using the DeviceMgr.GetDevice method.
3. Get an object for the element of the analog output subsystem that you want to use using the Device.AnalogOutputSubsystem method.
4. Set up the channel list (see page 380).
5. Set up common subsystem parameters (see page 382).
6. Set up the clocks (see page 383).
7. Set up the triggers (see page 384).
8. Set up buffering (see page 389).
10. Start the operation with the AnalogOutputSubsystem.Start method.
11. Deal with events and buffers (see page 394).
12. If desired, mute the output using the AnalogOutputSubsystem.Mute method.
13. Stop the operation (see page 397).
14. When done with your program, clean up the subsystem (see page 398).
Continuous, Interrupt-On-Change Digital Input Operations

1. If you haven’t already done so, get an object of type DeviceMgr using the `DeviceMgr.Get` method.

2. If you haven’t already done so, get an object of type Device for the specified hardware device using the `DeviceMgr.GetDevice` method.

5. Set the resolution of the subsystem using the `DigitalInputSubsystem.Resolution` property.

6. Select the digital input lines that you want to monitor for change of state using the `DigitalInputSubsystem.WriteInterruptOnChangeMask` method.

9. Go to the next page.
The InterruptOnChangeEventArgs class contains the subsystem that raised the event, the time stamp of when the event occurred, the digital input lines that changed state, and the current state of the digital input port.

Use the InterruptOnChangeHandler delegate to return the value of InterruptOnChangeEventArgs argument and to handle the event.

Wait for another interrupt?

Stop the operation (see page 397).

When done with your program, clean up the subsystem (see page 398).
**Event Counting Operations**

1. If you haven’t already done so, get an object of type DeviceMgr using the `DeviceMgr.Get` method.
2. If you haven’t already done so, get an object of type Device for the specified hardware device using the `DeviceMgr.GetDevice` method.
3. Get an object for the element of the counter/timer subsystem that you want to use using the `Device.CounterTimerSubsystem` method.
4. Specify the data flow mode to Continuous using the `CounterTimerSubsystem.DataFlow` property.
5. Specify the counter/timer mode as Count using the `CounterTimerSubsystem.CounterMode` property.
6. Set the cascade mode of the counter/timer subsystem to either Cascade for cascaded counter/timers or Single for non-cascaded counter/timers using the `CounterTimerSubsystem.CascadeMode`.
7. Set up the clocks and gates (see page 396).
8. Configure the subsystem using the `CounterTimerSubsystem.Config` method.
10. Go to the next page.
Read the current value of the counter/timer using the `CounterTimerSubsystem.ReadCount` method.

Get update of events total?

Yes

No

Stop the operation (see page 397).

When done with your program, clean up the subsystem (see page 399).
Up/Down Counting Operations

1. If you haven't already done so, get an object of type DeviceMgr using theDeviceMgr.Get method.

2. If you haven't already done so, get an object of type Device for the specified hardware device using theDeviceMgr.GetDevice method.

3. Get an object for the element of the counter/timer subsystem that you want to use using theDevice.CounterTimerSubsystem method.

4. Specify the data flow mode to Continuous using theCounterTimerSubsystem.DataFlow property.

5. Specify the counter/timer mode as UpDown using theCounterTimerSubsystem.CounterMode property.

6. Set the clock source to External using theClock.Source property.

7. Specify a clock divider to apply to the external clock source using theClock.ExtClockDivider property.

   The driver sets the actual clock divider as closely as possible to the number specified. You can read back the exact clock divider value after configuring the subsystem using theExtClockDivider property.

8. Configure the subsystem using theCounterTimerSubsystem.Config method.

10. Go to the next page.
Chapter 5

Continued from previous page.

Read the current value of the counter/timer using the \texttt{CounterTimerSubsystem.ReadCount} method.

Get update of events total? 

Yes

No

Stop the operation (see page 397).

When done with your program, clean up the subsystem (see page 399).
Edge-to-Edge Measurement Operations

If you haven’t already done so, get an object of type DeviceMgr using the `DeviceMgr.Get` method.

If you haven’t already done so, get an object of type Device for the specified hardware device using the `DeviceMgr.GetDevice` method.

Get an object for the element of the counter/timer subsystem that you want to use using the `Device.CounterTimerSubsystem` method.

Specify the data flow mode to Continuous using the `CounterTimerSubsystem.DataFlow` property.

Specify the counter/timer mode as Measure using the `CounterTimerSubsystem.CounterMode` property.

Set the clock source to Internal using the `Clock.Source` property.

Specify the start edge using the `CounterTimerSubsystem.StartEdge` property.

Specify the stop edge using the `CounterTimerSubsystem.StopEdge` property.

Configure the subsystem using the `CounterTimerSubsystem.Config` method.

Start the operation using the `CounterTimerSubsystem.Start` method.

To determine which edges are supported for the `StartEdge` and `StopEdge` properties, read the `CounterTimerSubsystem.SupportedEdgeTypes` property. This property returns an array of the supported signals/edges.

Note that if you want to perform another edge-to-edge measurement, you can call `Start` again.

Go to the next page.
The MeasureDoneEventArgs class contains the subsystem that raised the event, the timestamp of when the event occurred, and the value of the counter.

Use the `MeasureDoneHandler` delegate to receive the MeasureDoneEventArgs argument and to handle the event.

When done with your program, clean up the subsystem (see page 399).
Continuous Edge-to-Edge Measurement Operations

- If you haven’t already done so, get an object of type `DeviceMgr` using the `DeviceMgr.Get` method.

- If you haven’t already done so, get an object of type `Device` for the specified hardware device using the `DeviceMgr.GetDevice` method.

- Get an object for the element of the counter/timer subsystem that you want to use using the `Device.CounterTimerSubsystem` method.

- Specify the data flow mode to Continuous using the `CounterTimerSubsystem.DataFlow` property.

- Specify the counter/timer mode as ContinuousMeasure using the `CounterTimerSubsystem.CounterMode` property.

- Set the clock source to Internal using the `Clock.Source` property.

- Specify the start edge using the `CounterTimerSubsystem.StartEdge` property.

- Specify the stop edge using the `CounterTimerSubsystem.StopEdge` property.

- Configure the subsystem using the `CounterTimerSubsystem.Config` method.

- Start the operation using the `CounterTimerSubsystem.Start` method.

- Go to the next page.

To determine which edges are supported for the `StartEdge` and `StopEdge` properties, read the `CounterTimerSubsystem.SupportedEdgeTypes` property. This property returns an array of the supported signals/edges.
Read the value of the counter/timer using the `CounterTimerSubsystem.ReadCount` method or through the channel list of the `AnalogInputSubsystem` class.

On each read of the counter/timer, the current value of the counter/timer channel is returned and the next edge-to-edge measurement mode operation starts. If the current edge-to-edge measurement operation is still in progress, 0 is returned.

When done with your program, clean up the subsystem (see page 399).
Pulse Output Operations

If you haven’t already done so, get an object of type DeviceMgr using the DeviceMgr.Get method.

If you haven’t already done so, get an object of type Device for the specified hardware device using the DeviceMgr.GetDevice method.

Get an object for the element of the counter/timer subsystem that you want to use using the Device.CounterTimerSubsystem method.

Specify the data flow mode to Continuous using the CounterTimerSubsystem.DataFlow property.

Specify the counter/timer mode as one of the following values using the CounterTimerSubsystem.CounterMode property: RateGenerator for continuous output pulses, OneShot for a single output pulse, or OneShotRepeat for repetitive single output pulses.

Set the cascade mode of the counter/timer subsystem to either Cascade for cascaded counter/timers or Single for non-cascaded counter/timers using the CounterTimerSubsystem.CascadeMode property.

Set up the clocks and gates (see page 396).

Specify the output pulse type using the CounterTimerSubsystem.PulseType property.

Specify the duty cycle of the output pulse using the CounterTimerSubsystem.PulseWidth property.

Configure the subsystem using the CounterTimerSubsystem.Config method.

Go to the next page.
Continued from previous page.

Start the operation using the `CounterTimerSubsystem.Start` method.

Stop the operation (see page 397).

When done with your program, clean up the subsystem (see page 399).

This step is not needed for single one-shot operations.
Measure Counter Operations

If you haven’t already done so, get an object of type DeviceMgr using the `DeviceMgr.Get` method.

If you haven’t already done so, get an object of type Device for the specified hardware device using the `DeviceMgr.GetDevice` method.

Get an object for the element of the counter/timer subsystem that you want to use using the `Device.CounterTimerSubsystem` method.

Specify the start edge using the `CounterTimerSubsystem.StartEdge` property.

Specify the stop edge using the `CounterTimerSubsystem.StopEdge` property.

Configure the subsystem using the `CounterTimerSubsystem.Config` method.

Read the value of the counter/timer using the `CounterTimerSubsystem.ReadCount` method or through the channel list of the AnalogInputSubsystem class.

When done with your program, clean up the subsystem (see page 399).

To determine which edges are supported for the `StartEdge` and `StopEdge` properties, read the `CounterTimerSubsystem.SupportedEdgeTypes` property. This property returns an array of the supported signals/edges.
Tachometer Operations

1. Get an object for the element of the tachometer subsystem that you want to use using the `DeviceMgr.TachSubsystem` method.

2. Get an object of type `DeviceMgr` using the `DeviceMgr.Get` method.

4. Use the `TachSubsystem.EdgeType` property to specify a rising or falling edge for the tachometer operation.

5. Use the `TachSubsystem.StaleDataFlagEnabled` property to specify the value of the stale data flag. If this flag is True, the most significant bit (MSB) of the value is set to 0 to indicate new data; reading the value before the measurement is complete returns an MSB of 1. If this flag is False, the MSB is always set to 0.

7. Read the value of the tachometer using the `TachSubsystem.Count` property or from the analog input stream by adding the tachometer in the analog input channel list. Follow the steps for continuous analog input operations, on page 356.

8. If desired, use `OIBuffer.GetDataAsRpm` to convert the data to RPM values and copy the data as an array of 64-bit floating-point values.

9. When done with your program, clean up the subsystem (see page 399).
Quadrature Decoder Operations

If you haven’t already done so, get an object of type DeviceMgr using the DeviceMgr.Get method.

If you haven’t already done so, get an object of type Device for the specified hardware device using the DeviceMgr.GetDevice method.

Get an object for the element of the counter/timer subsystem that you want to use using the Device.QuadratureDecoderSubsystem method.

Specify the data flow mode to Continuous using the QuadratureDecoderSubsystem.DataFlow property.

Set the clock source to External using the QuadratureDecoderSubsystem.Clock.Source property.

Set the pre-scale value used to divide the base clock frequency using the QuadratureDecoderSubsystem.ClockPreScale property.

Set the value of the QuadratureDecoderSubsystem.X4Scaling property to True if you want to use X4 mode, or False if you want to use X1 mode.

Set the value of the QuadratureDecoderSubsystem.IndexMode property to Disabled if you do not want to use the Index input signal, Low if the Index input signal is low, or High if the Index input signal is high.

Configure the subsystem using the QuadratureDecoderSubsystem.Config method.

Start the operation using the QuadratureDecoderSubsystem.Start method.

Go to the next page.
Continued from previous page.

Read the current value of the quadrature decoder using the \texttt{QuadratureDecoderSubsystem. ReadCount} method.

Get update of events total?

Yes

No

Stop the operation (see page 397).

When done with your program, clean up the subsystem (see page 399).
Simultaneously Starting Subsystems

1. Configure the subsystem that you want to run simultaneously.

2. Add the specified subsystem to the list of subsystems to simultaneous start using the `SimultaneousStart.AddSubsystem` method.

3. Prestart the subsystems on the simultaneous start list using the `SimultaneousStart.PreStart` method.

4. Start the subsystems on the simultaneous start list using the `SimultaneousStart.Start` method.

5. Deal with events (see page 390 for analog input operations; see page 394 for analog output operations).

6. Stop the operation (see page 397).

7. When done with your program, clean up the subsystem (see page 398 for analog I/O operations).

See the previous flow diagrams in this chapter; you cannot perform single-value operations simultaneously on multiplexed A/D modules.
Set Up Analog Input Channels

Set up the channel name?

Yes

Use the **SupportedChannelInfo.Name** property to set the channel name.

No

Is IOType MultiSensor?

Yes

Use the **SupportedChannelInfo.MultiSensorType** property to set the sensor type for each channel.

No

Voltage Input Channel?

Yes

If supported, use the **SupportedChannelInfo.InputTerminationEnabled** property to enable or disable use of the bias return termination resistor based on the channel wiring.

If desired, use the **SupportedChannelInfo.SensorGain** and **SupportedChannelInfo.SensorOffset** properties to set the gain and offset for the sensor connected to the channel.

No

Thermocouple channel?

Yes

Use the **SupportedChannelInfo.ThermocoupleType** property to set the thermocouple type.

No

RTD channel?

Yes

Use the **SupportedChannelInfo.RTDTType** property to set the RTD type.

- If the RTD type is Pt3850 or Custom, use the **SupportedChannelInfo.RtdR0** property to set the resistance value of the RTD.
- If the RTD type is Custom, use the **SupportedChannelInfo.RtdACoefficient**, **RtdBCoefficient**, and **RtdCCoefficient** properties to set the Callendar-Van Dusen coefficients for the RTD.

No

Use the **SupportedChannelInfo.SensorWiringConfiguration** property to indicate whether the RTD uses a two-wire, three-wire, or four-wire configuration.

Go to next page.
Use the `SupportedChannelInfo.ThermistorACoefficient`, `ThermistorBCoefficient`, and `ThermistorCCoefficient` properties to set the Steinhart-Hart coefficients for the thermistor.

Use the `SupportedChannelInfo.SensorWiringConfiguration` property to indicate whether the thermistor uses a two-wire, three-wire, or four-wire configuration.

Use the `SupportedChannelInfo.ExcitationCurrentSource` property to set the excitation current source to Internal, External, or Disabled.

Use the `SupportedChannelInfo.ExcitationCurrentValue` property to set the value of the internal excitation current source based on the resistor that is used.

If supported, use the `SupportedChannelInfo.InputTerminationEnabled` property to enable or disable use of the bias return termination resistor based on the channel wiring.

Use the `SupportedChannelInfo.Coupling` property to set the coupling type to AC or DC.

Use the `SupportedChannelInfo.ExcitationCurrentSource` property to set the excitation current source to Internal, External, or Disabled.

Use the `SupportedChannelInfo.ExcitationCurrentValue` property to set the value of the internal excitation current source.
Continued from previous page.

Use the `SupportedChannelInfo.StrainGageBridgeConfiguration` property to set the strain gage configuration.

Use the `SupportedChannelInfo.StrainGagePoissonRatio` property to set the Poisson ratio for bridge configurations that measure the Poisson effect.

Use the `SupportedChannelInfo.StrainGageLeadWireResistance` property to set the lead wire resistance if remote sensing is not used.

Use the `SupportedChannelInfo.StrainGageGageFactor` property to set the gage factor for the strain gage.

Use the `SupportedChannelInfo.StrainGageNominalResistance` property to set the nominal resistance for the strain gage.

Perform offset nulling?

Yes

Read the value of the bridge in an unstrained condition using the `AnalogInputSubsystem.GetSingleValueAsVolts` method.

Specify the value that you read using the `SupportedChannelInfo.StrainGageOffsetNullingValueInVolts` property.

To use an internal shunt calibration resistor, if supported, enable the resistor by setting the `SupportedChannelInfo.StrainGageShuntCalibrationResistorEnabled` property to True.

Read the value of the bridge using the `AnalogInputSubsystem.GetSingleValueAsStrain` method.

Divide the expected value of the bridge by the actual value that you read, and specify the result, in microstrain, using the `SupportedChannelInfo.StrainGageShuntCalibrationValue` property.

If using an internal shunt resistor, disable the shunt resistor by setting the `SupportedChannelInfo.StrainGageShuntCalibrationResistorEnabled` property to False.

No

Perform shunt calibration?

Yes

No
For full-bridge based sensors, such as load cells, use the `SupportedChannelInfo.TransducerCapacity` property to set the full-scale range of the transducer in its native engineering units and use the `SupportedChannelInfo.TransducerRatedOutputinMv` property to set the rated output of the transducer in terms of mV/V excitation.

Use the `SupportedChannelInfo.BridgeConfiguration` property to set the bridge configuration.

Use the `AnalogInputSubsystem.ExcitationVoltageSource` property to specify the excitation voltage source as internal, external, or disabled.

If the internal excitation voltage source is used, use the `AnalogInputSubsystem.ExcitationVoltageValue` property to set the excitation voltage value.

Use the `SupportedChannelInfo.StrainGageLeadWireResistance` property to set the lead wire resistance.

Use the `SupportedChannelInfo.StrainGageNominalResistance` property to set the nominal resistance.

Read the value of the bridge in an unstrained condition using the `AnalogInputSubsystem.GetSingleValueAsStrain` method.

Specify the value that you read using the `SupportedChannelInfo.StrainGageOffsetNullingValueInVolts` property.

To use an internal shunt calibration resistor, if supported, enable the resistor using the `SupportedChannelInfo.StrainGageShuntCalibrationResistorEnabled` property.

Read the value of the bridge using the `AnalogInputSubsystem.GetSingleValueAsStrain` method.

Divide the expected value of the bridge by the actual value that you read, and specify the result, in microstrain, using the `SupportedChannelInfo.StrainGageShuntCalibrationValue` property.

If using an internal shunt resistor, disable the shunt resistor by setting the `SupportedChannelInfo.StrainGageShuntCalibrationResistorEnabled` property to False.
Set Up the ChannelList

Set up the channel to read (see page 376).

Add a channel by ChannelListEntry ?

Yes

Go to the top of page 381.

The channel is appended to the end of the channel list. A ChannelListEntry object is returned.

No

Add a channel by physical channel number or name to the ChannelList using the ChannelList.Add method.

Set the gain of the specified ChannelListEntry object using the ChannelListEntry.Gain property.

Specify whether to inhibit returning data for the specified ChannelListEntry object using the ChannelListEntry.Inhibit property.

Yes

Add another channel to the list?

The driver sets the actual gain as closely as possible to the number specified. You can read back the exact gain after configuring the subsystem using the Gain property.

If inhibited, the values for the specified channel object are acquired, and then discarded.
Add a Channel by ChannelListEntry

Use the ChannelListEntry constructor within the ChannelListEntry class to create and return a ChannelListEntry object that is associated with a SupportedChannelInfo object for the specified subsystem and Device object.

Set the gain of the specified ChannelListEntry object using the ChannelListEntry.Gain property.

Specify whether to inhibit returning data for the specified ChannelListEntry object using the ChannelListEntry.Inhibit property.

Yes

Define another channel?

No

Add the ChannelListEntry to the ChannelList using the ChannelList.Add method.

Yes

Add another channel to the list?

The driver sets the actual gain as closely as possible to the number specified. You can read back the exact gain after configuring the subsystem using the Gain property.

If inhibited, the values for the specified channel object are acquired, and then discarded.

The channel is appended to the end of the channel list.
Set up Common Subsystem Parameters

Set the channel type of the subsystem to SingleEnded or Differential using the ChannelType property within the appropriate subsystem class.

Set the data encoding of the subsystem to Binary or TwosComplement using the Encoding property within the appropriate subsystem class.

Set the voltage range of the subsystem using the VoltageRange property within the appropriate subsystem class.

Does the subsystem support strain gages or bridges?

Yes

Set the excitation voltage source using the AnalogInputSubsystem.ExcitationVoltageSource property.

Is excitation source Internal?

Yes

Set the value of the internal excitation voltage source using the AnalogInputSubsystem.ExcitationVoltageValue property.

No

Does the subsystem support synchronization through the Sync Bus?

Yes

Set the synchronization mode of the subsystem to None, Master, or Slave using the SynchronizationMode property.

No

Does the subsystem support filters?

Yes

Set the filter type of the subsystem to Raw or MovingAverage using the AnalogInputSubsystem.DataFilterType property.

No
**Set Up Clocks**

**Using an internal clock?**

**Yes**
- Set the clock source to Internal using the `Clock.Source` property.
- Set the frequency of the internal clock using the `Clock.Frequency` property.

The driver sets the actual frequency as closely as possible to the number specified. You can read back the exact frequency after configuring the subsystem using the `Frequency` property.

**No**
- Set the clock source to External using the `Clock.Source` property.
- Specify a clock divider to apply to the external clock source using the `Clock.ExtClockDivider` property.

The driver sets the actual clock divider as closely as possible to the number specified. You can read back the exact clock divider value after configuring the subsystem using the `ExtClockDivider` property.
Set Up Triggers

Using a start trigger and reference trigger for pre-trigger/post-trigger operations?

- Yes
  - Set the start trigger type to one of the following values (if supported by your device) using the `AnalogInputSubsystem.Trigger.TriggerType` property:
    - Software for a software (internal) trigger,
    - TTLPos for an external TTL low-to-high trigger,
    - DigitalEvent for a digital event trigger,
    - TTLNeg for an external TTL high-to-low trigger,
    - ThresholdPos for a positive-going threshold trigger,
    - ThresholdNeg for a negative-going threshold trigger.

- No
  - No

Using threshold trigger for the start trigger?

- Yes
  - Set the channel to use for the threshold trigger using the `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` property.

- No
  - Set the level of the threshold trigger using the `AnalogInputSubsystem.Trigger.Level` property.

Set the reference trigger source to one of the following values using the `AnalogInputSubsystem.ReferenceTrigger.TriggerType` property:

- Software for a software (internal) trigger,
- TTLPos for an external TTL low-to-high trigger,
- DigitalEvent for a digital event trigger,
- TTLNeg for an external TTL high-to-low trigger,
- ThresholdPos for a positive-going threshold trigger,
- ThresholdNeg for a negative-going threshold trigger,
- Sync Bus for a Sync Bus trigger.

This trigger source stops pre-trigger acquisition, if in progress, and starts post-trigger acquisition.

Using threshold trigger for the reference trigger?

- Yes
  - Set the channel to use for the threshold trigger using the `AnalogInputSubsystem.ReferenceTrigger.ThresholdTriggerChannel` property.

- No
  - Set the level of the threshold trigger using the `AnalogInputSubsystem.ReferenceTrigger.Level` property.

Specify the number of samples to acquire after the reference trigger using the `AnalogInputSubsystem.ReferenceTrigger.PostTriggerScanCount` property.

Go to next page.
Set the pre-trigger type to one of the following values (if supported by your device) using `AnalogInputSubsystem.Trigger.PreTriggerSource` property:
Software for a software (internal) trigger, TTLPos for an external TTL low-to-high trigger, DigitalEvent for a digital event trigger, TTLNeg for an external TTL high-to-low trigger, ThresholdPos for a positive-going threshold trigger, or ThresholdNeg for a negative-going threshold trigger.

If supported by your device, set the channel to use for the threshold trigger using the `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` property.

If supported by your device, set the level of the threshold trigger using the `AnalogInputSubsystem.Trigger.Level` property.

Set the post-trigger source to one of the following values (if supported by your device) using `AnalogInputSubsystem.Trigger.TriggerType` property:
Software for a software (internal) trigger, TTLPos for an external TTL low-to-high trigger, DigitalEvent for a digital event trigger, TTLNeg for an external TTL high-to-low trigger, ThresholdPos for a positive-going threshold trigger, or ThresholdNeg for a negative-going threshold trigger. This trigger source stops pre-trigger acquisition, if in progress, and starts post-trigger acquisition.

If supported by your device, set the channel to use for the threshold trigger using the `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` property.

If supported by your device, set the level of the threshold trigger using the `AnalogInputSubsystem.Trigger.Level` property.

Using threshold trigger?

No
Using a trigger to start analog output operations?

Set the trigger source to one of the following values (if supported by your device) using the `AnalogOutputSubsystem.Trigger.TriggerType` property: Software for a software (internal) trigger, TTLPos for an external TTL low-to-high trigger, DigitalEvent for a digital event trigger, TTLNeg for an external TTL high-to-low trigger, ThresholdPos for a positive-going threshold trigger, or ThresholdNeg for a negative-going threshold trigger.

Using threshold trigger?

If supported by your device, set the channel to use for the threshold trigger using the `AnalogOutputSubsystem.Trigger.ThresholdTriggerChannel` property.

If supported by your device, set the level of the threshold trigger using the `AnalogOutputSubsystem.Trigger.Level` property.
Set Up Triggered Scan

Enable triggered scan mode using the `TriggeredScan.Enabled` property.

Set the retrigger source to one of the following values using the `TriggeredScan.RetriggerSource` property: Software for a software (internal) trigger, TTLPos for an external TTL low-to-high trigger, DigitalEvent for a digital event trigger, TTLNeg for an external TTL high-to-low trigger, ThresholdPos for a positive-going threshold trigger, or ThresholdNeg for a negative-going threshold trigger.

Set the frequency of the retrigger clock using the `TriggeredScan.RetriggerFrequency` property.

Specify the number of times to scan the channel list per retrigger using the `TriggeredScan.MultiScanCount` property.

The driver sets the actual frequency as closely as possible to the number specified. You can read back the exact frequency after configuring the subsystem using the `RetriggerFrequency` property.

The channel is retriggered at the frequency of the retrigger clock.
Set Up Input Buffering

Use the `OlBuffer` constructor within the OlBuffer class to create an OlBuffer object and allocate an internal data buffer for use with an analog input subsystem.

Use the `AnalogInputSubsystem.BufferQueue.QueueBuffer` method to add the OlBuffer object to the queue for the analog input subsystem.

Continuous input operations require a minimum of two OlBuffer objects.

During this step, you also determine the size of the internal data buffer by specifying the number of samples in the buffer (each sample typically requires 2 bytes).

Allocate another buffer?

Yes
Set Up Output Buffering

Use the `OlBuffer` constructor within the OlBuffer class to create an OlBuffer object and allocate an internal data buffer for use with an analog output subsystem.

Create a user-specified array with the data to output.

Copy data from the user-specified array into the internal buffer of the OlBuffer object using one of the following methods: `OlBuffer.PutDataAsRaw` (to output raw counts) or `OlBuffer.PutDataAsVolts` (to output voltages).

Add the OlBuffer object to the queue for the analog output subsystem using the `AnalogOutputSubsystem.BufferQueue.QueueBuffer` method.

Yes

Allocate another buffer?

No

Set the buffer wrap mode of the analog output subsystem to True or False using the `AnalogOutputSubsystem.WrapSingleBuffer` property.

During this step, you also determine the size of the internal buffer by specifying the number of samples in the buffer (each sample typically requires 2 bytes).

Continuous output operations require two OlBuffer objects if `WrapSingleBuffer` is False (one if `WrapSingleBuffer` is True).

By default, `WrapSingleBuffer` is False. In this state, data is written from the allocated buffers continuously. As each buffer is emptied, a BufferDone event occurs. If no more buffers are available and queued to the subsystem, the operation stops.

If you set `WrapSingleBuffer` to True, the device driver continuously reuses the first buffer queued to the analog output subsystem. Data from a single output buffer is downloaded to the FIFO of the device (if supported by the device) and is written out starting from the first location of the buffer; when the end of the buffer is reached, the device starts outputting data from the first location of the buffer, and the process repeats.
Deal with Events and Buffers for Input Operations

PreTriggerBufferDoneEvent raised?

Yes

Use the PreTriggerBufferDoneHandler delegate to receive the BufferDoneEventArgs argument and handle the buffer.

No

OIBuffer ValidSamples > 0?

Yes

Declare a user-specified array of the appropriate type (determined by the method used next).

No

Copy the data from the internal buffer of an OIBuffer object to a user-specified array using
- OIBuffer.GetDataAsRawByte (converts to raw counts and copies into an array of bytes),
- OIBuffer.GetDataAsRawInt16 (converts two's complement data into raw counts when the resolution is 16 bits or less and copies into an array of signed, 16-bit integers),
- OIBuffer.GetDataAsRawUInt16 (converts binary data into raw counts when the resolution is 16 bits or less and copies into an array of unsigned 16-bit integers),
- OIBuffer.GetDataAsRawUInt32 (converts to raw counts when the resolution is more than 16-bits and copies into an array of unsigned 32-bit integers),
- OIBuffer.GetDataAsVolts (converts to voltage and copies into an array of floating-point values),
- OIBuffer.GetDataAsVoltsByte (converts to voltage and copies into an array of bytes),
- OIBuffer.GetDataAsSensor (converts to sensor values and copies into an array of floating-point values),
- OIBuffer.GetDataAsResistance (converts to ohms and copies into an array of floating-point values),
- OIBuffer.GetDataAsCurrent (converts to amperes and copies into an array of floating-point values),
- OIBuffer.GetDataAsTemperatureByte (converts to temperature and copies into an array of bytes),
- OIBuffer.GetDataAsTemperatureDouble (converts to temperature and copies into an array of floating-point values),
- OIBuffer.GetDataAsRpm (converts to RPM values and copies into an array of floating-point values),
- OIBuffer.GetDataAsStrain (converts to microstrain values and copies into an array of floating-point values),
- OIBuffer.GetDataAsBridgeBasedSensor (converts to the engineering values of the full-bridge-based sensor and copies into an array of floating-point values), or
- OIBuffer.GetDataAsNormalizedBridgeOutput (converts to mV/Vexe and copies into an array of floating-point values).

Process the data in your program.

Add the OIBuffer object to the queue for the analog input subsystem using the BufferQueue.QueueBuffer method.

Transfer Data from an Inprocess Buffer

- Create an OlBuffer object to hold the data that you want to move using the OlBuffer constructor.
- Check the state of the OlBuffer object that is being filled using the OlBuffer.State property.
- Is OlBuffer Inprocess?
  - Yes: Move the data from the internal buffer of the OlBuffer object that is currently being filled to the internal buffer of a new OlBuffer object using the AnalogInputSubsystem. MoveFromBufferInprocess method.
  - No: A BufferDoneEvent is generated when the operation completes.
- See page 390 to deal with the buffers and events.
Deal with Events and Buffers for Output Operations

BufferDoneEvent raised?

Yes

Use the BufferDoneHandler delegate to receive the BufferDoneEventArgs argument and handle the buffer.

No

Refill buffers?

Yes

Create a user-specified array of the appropriate type with the data to output (determined by the method used next).

No

Copy data from a user-specified array into the internal buffer of the OlBuffer object using one of the following methods: OlBuffer.PutDataAsRaw (to output raw counts) or OlBuffer.PutDataAsVolts (to output voltages).

Add the OlBuffer object to the queue for the analog output subsystem using the AnalogOutputSubsystem.BufferQueue.QueueBuffer method.

Set the AnalogOutputSubsystem.WrapSingleBuffer property to True if you want the device driver to continuously reuse the first OlBuffer object queued to the subsystem.

Set Clocks and Gates for Counter/Timer Operations

Using an internal clock?

Yes

Set the clock source to Internal using the **Clock.Source** property.

Set the frequency of the output pulse from the internal clock using the **Clock.Frequency** property.

The driver sets the actual frequency as closely as possible to the number specified. You can read back the exact frequency after configuring the subsystem using the **Frequency** property.

No

Set the clock source to External using the **Clock.Source** property.

Specify a clock divider to apply to the external clock source using the **Clock.ExtClockDivider** property. This sets the frequency of the output pulse.

The driver sets the actual clock divider as closely as possible to the number specified. You can read back the exact clock divider value after configuring the subsystem using the **ExtClockDivider** property.

Set the gate type to one of the following values using the **CounterTimerSubsystem.GateType** property: None for a software gate, HighLevel for a high-level gate, LowLevel for a low-level gate, HighEdge for a high-edge gate, LowEdge for a low-edge gate, or Level for any level gate.
**Stop the Operation**

Stop in an orderly way?

- **Yes**
  - Use the **Stop** method within the appropriate subsystem class to stop the operation after the current buffer has been completed.
  - The driver posts at least one BufferDoneEvent and QueueStoppedEvent events.

- **No**
  - Reinitialize subsystem?
    - **Yes**
      - Use the **Reset** method within the appropriate subsystem class to stop the operation immediately without waiting for the current buffer to be completed, and reinitialize the subsystem to the default configuration.
    - **No**
      - Use the **Abort** method within the appropriate subsystem class to stop the operation immediately without waiting for the current buffer to be completed.
**Clean Up Single-Value I/O Operations**

Release the subsystem connection to the hardware device using the `Dispose` method within the appropriate subsystem class.

Release the device using the `Device.Dispose` method.

**Clean Up Buffered I/O Operations**

Remove all OlBuffer objects queued to the subsystem and deallocate the associated internal buffers using the `BufferQueue.FreeAllQueueBuffers` method.

For simultaneous operations only, clear the simultaneous start list using the `SimultaneousStart.Clear` method.

Release the subsystem connection to the hardware device using the `Dispose` method within the appropriate subsystem class.

Release the device using the `Device.Dispose` method.

**Clean Up Digital I/O Operations**

For simultaneous operations only, clear the simultaneous start list using the `SimultaneousStart.Clear` method.

Release the subsystem connection to the hardware device using the `Dispose` method within the appropriate subsystem class.

Release the device using the `Device.Dispose` method.
**Clean Up Counter/Timer Operations**

For simultaneous operations only, clear the simultaneous start list using the `SimultaneousStart.Clear` method.

Release the subsystem connection to the hardware device using the `CounterTimerSubsystem.Dispose` method.

Release the device using the `Device.Dispose` method.

**Clean Up Quadrature Decoder Operations**

For simultaneous operations only, clear the simultaneous start list using the `SimultaneousStart.Clear` method.

Release the subsystem connection to the hardware device using the `QuadratureDecoderSubsystem.Dispose` method.

Release the device using the `Device.Dispose` method.

**Clean Up Tachometer Operations**

Release the subsystem connection to the hardware device using the `TachSubsystem.Dispose` method.

Release the device using the `Device.Dispose` method.

The flowcharts presented in the remainder of this chapter show how to perform typical input/output operations using the OpenLayers.DeviceCollection namespace.

**Note:** Depending on your device, some of the settings may not be programmable. Refer to your device documentation for details.

Although the flowcharts do not show error checking, it is recommended that you add exception handling to your program.

Some steps represent several substeps; if you are unfamiliar with the detailed operations involved with any one step, refer to the indicated page for detailed information.
Single-Value Analog Input Operations

If you haven't already done so, get an object of type DeviceMgr using the `DeviceMgr.Get` method.

If you haven't already done so, get an object of type Device for the specified device collection using the `DeviceMgr.GetDevice` method.

Get an object for each element of the subsystem that you want to use using the `Device.AnalogInputSubsystem` method.

Set the data flow mode to SingleValue using the `AnalogInputSubsystem.DataFlow` property.

Set up the analog input channel (see page 411).

Set up the common subsystem parameters (see page 414).

Configure the subsystem using the `AnalogInputSubsystem.Config` method.

Acquire a single value using one of the following methods:
- `AnalogInputSubsystem.GetSingleValueAsRaw` (for a raw count),
- `AnalogInputSubsystem.GetSingleValueAsVolts` (for a voltage value),
- `AnalogInputSubsystem.GetSingleValueAsSensor` (for a sensor value).

Acquire another value?

Yes

No

When done with your program, clean up the subsystem (see page 426).
Single-Value Analog Output Operations

1. If you haven’t already done so, get an object of type DeviceMgr using the `DeviceMgr.Get` method.

2. If you haven’t already done so, get an object of type Device for the specified device collection using the `DeviceMgr.GetDevice` method.

3. Get an object for each element of the subsystem that you want to use using the `Device.AnalogOutputSubsystem` method.

5. Set the common subsystem parameters (see page 414).

6. Configure the subsystem using the `AnalogOutputSubsystem.Config` method.

7. Does subsystem support simultaneous output?
   - Yes
     - Output a single value to each output channel using one of the following methods:
       - `AnalogOutputSubsystem.SetSingleValuesAsRaw` (to output raw counts) or
       - `AnalogOutputSubsystem.SetSingleValuesAsVolts` (to output voltages).

   - No
     - Output a single value using one of the following methods:
       - `AnalogOutputSubsystem.SetSingleValueAsRaw` (to output a raw count) or
       - `AnalogOutputSubsystem.SetSingleValueAsVolts` (to output a voltage).

8. When done with your program, clean up the subsystem (see page 426).
Continuous Analog Input Operations - One Buffer

If you haven't already done so, get an object of type DeviceMgr using the `DeviceMgr.Get` method.

If you haven't already done so, get an object of type Device for the specified device collection using the `DeviceMgr.GetDevice` method.

Get an object for the element of the analog input subsystem that you want to use using the `Device.AnalogInputSubsystem` method.

Use the `AnalogInputSubsystem.DataFlow` property to set the data flow mode to Continuous.

Set up the analog input channel (see page 411).

Add a single channel to the ChannelList (see page 412).

Set up common subsystem parameters (see page 414).

Set up the clocks (see page 415).

Set up the triggers (see page 416). Note that reference triggers are not supported for this operation type.

Configure the subsystem using the `AnalogInputSubsystem.Config` method.

Call the `AnalogInputSubsystem.GetOneBuffer` method to acquire one buffer of data from the specified analog input channel.

Go to the next page.
Copy the data from the internal buffer of an OlBuffer object to a user-specified array using
- `OlBuffer.GetDataAsRawByte` (converts to raw counts and copies into an array of bytes),
- `OlBuffer.GetDataAsRawInt16` (converts two's complement data into raw counts when the
  resolution is 16 bits or less and copies into an array of signed, 16-bit integers),
- `OlBuffer.GetDataAsRawUInt16` (converts binary data into raw counts when the resolution is
  16 bits or less and copies into an array of unsigned 16-bit integers),
- `OlBuffer.GetDataAsRawUInt32` (converts to raw counts when the resolution is more than
  16-bits and copies into an array of unsigned 32-bit integers),
- `OlBuffer.GetDataAsVolts` (converts to voltage and copies into an array of floating-point values),
- `OlBuffer.GetDataAsVoltsByte` (converts to voltage and copies into an array of bytes),
- `OlBuffer.GetDataAsSensor` (converts to sensor values and copies into an array of
  floating-point values), or
- `OlBuffer.GetDataAsRpm` (converts to RPM values and copies into an array of
  floating-point values).

When done with your program, clean up the subsystem
(see page 426).
Continuous Analog Input Operations - Multiple Buffers

1. If you haven’t already done so, get an object of type DeviceMgr using the DeviceMgr.Get method.
2. If you haven’t already done so, get an object of type Device for the specified device collection using the DeviceMgr.GetDevice method.
3. Get an object for the element of the analog input subsystem that you want to use using the Device.AnalogInputSubsystem method.
4. Use the AnalogInputSubsystem.DataFlow property to set one of the following data flow modes: Continuous for post-trigger operations, ContinuousPreTrigger for continuous pre-trigger operations, or ContinuousPrePostTrigger for continuous about-trigger operations.
5. Set up the analog input channels (see page 411).
6. Set up the ChannelList (see page 412).
7. Set up common subsystem parameters. (see page 414).
8. Set up the clocks (see page 415).
9. Set up the triggers (see page 416).
10. Set up buffering (see page 418).
11. Configure the subsystem using the AnalogInputSubsystem.Config method.

Go to the next page.
Deal with events and buffers (see page 420).

Stop the operation (see page 425).

When done with your program, clean up the subsystem (see page 426).

Configure the subsystem to execute BufferDoneEvent events synchronously in a single thread using the `AnalogInputSubsystem.SynchronousBufferDone` property.

Start the operation with the `AnalogInputSubsystem.Start` method.

Deal with events and buffers (see page 420).
Continuous Analog Output Operations

If you haven’t already done so, get an object of type DeviceMgr using the `DeviceMgr.Get` method.

If you haven’t already done so, get an object of type Device for the specified device collection using the `DeviceMgr.GetDevice` method.

Get an object for the element of the analog output subsystem that you want to use using the `Device.AnalogOutputSubsystem` method.

Set the data flow mode to Continuous using the `AnalogOutputSubsystem.DataFlow` property.

Set up common subsystem parameters (see page 414).

Set up the channel list (see page 412).

Set up the clocks (see page 415).

Set up the triggers (see page 416).

Set up buffering (see page 419).

Configure the subsystem using the `AnalogOutputSubsystem.Config` method.

Start the operation with the `AnalogOutputSubsystem.Start` method.

Deal with events and buffers (see page 423).

If desired, mute the output using the `AnalogOutputSubsystem.Mute` method.

Stop the operation (see page 425).

When done with your program, clean up the subsystem (see page 426).
Simultaneously Starting Subsystems

1. Configure the subsystem that you want to run simultaneously.
2. Add the specified subsystem to the list of subsystems to simultaneous start using the `SimultaneousStart.AddSubsystem` method.
3. Prestart the subsystems on the simultaneous start list using the `SimultaneousStart.PreStart` method.
4. Start the subsystems on the simultaneous start list using the `SimultaneousStart.Start` method.
5. Deal with events (see page 420 for analog input operations; see page 423 for analog output operations).
6. Stop the operation (see page 425).
7. When done with your program, clean up the subsystem (see page 426 for analog I/O operations).

See the previous flow diagrams in this chapter; you cannot perform single-value operations simultaneously on multiplexed A/D modules.
Set Up Analog Input Channels

Set up the channel name?

Yes

Use the `SupportedChannelInfo.Name` property to set the channel name.

No

Voltage Input Channel?

Yes

If desired, use the `SupportedChannelInfo.SensorGain` and `SupportedChannelInfo.SensorOffset` properties to set the gain and offset for the sensor connected to the channel.

No

Accelerometer channel?

Yes

Use the `SupportedChannelInfo.Coupling` property to set the coupling type to AC or DC.

Use the `SupportedChannelInfo.ExcitationCurrentSource` property to set the excitation current source to Internal, External, or Disabled.

No

Excitation internal?

Yes

Use the `SupportedChannelInfo.ExcitationCurrentValue` property to set the value of the internal excitation current source.
Set Up the ChannelList

Set up the channel to read (see page 411).

Add a channel by physical channel number or name to the ChannelList using the ChannelList.Add method. The channel is appended to the end of the channel list. A ChannelListEntry object is returned.

Add another channel to the list? Yes

Ye s

If inhibited, the values for the specified channel object are acquired, and then discarded.

Set the gain of the specified ChannelListEntry object using the ChannelListEntry.Gain property.

Specify whether to inhibit returning data for the specified ChannelListEntry object using the ChannelListEntry.Inhibit property.

Yes

Add another channel to the list?

Go to the top of page 413.

No

The driver sets the actual gain as closely as possible to the number specified. You can read back the exact gain after configuring the subsystem using the Gain property.

If inhibited, the values for the specified channel object are acquired, and then discarded.

At least one channel from the master device in the device collection must be added to the channel list.

If supported by your device, you can add a non-native channel (such as the digital I/O port, counter/timer, or tachometer) to the channel list. However, you must configure these channels using the OpenLayers.Base namespace. See Chapter 5 starting on page 347 for more information.

Set up the channel to read (see page 411).

Add a channel by physical channel number or name to the ChannelList using the ChannelList.Add method.

Set the gain of the specified ChannelListEntry object using the ChannelListEntry.Gain property.

Specify whether to inhibit returning data for the specified ChannelListEntry object using the ChannelListEntry.Inhibit property.

Add another channel to the list?
Add a Channel by ChannelListEntry

Use the `ChannelListEntry` constructor within the `ChannelListEntry` class to create and return a `ChannelListEntry` object that is associated with a `SupportedChannelInfo` object for the specified subsystem and Device object.

Set the gain of the specified `ChannelListEntry` object using the `ChannelListEntry.Gain` property.

Specify whether to inhibit returning data for the specified `ChannelListEntry` object using the `ChannelListEntry.Inhibit` property.

Add the `ChannelListEntry` to the `ChannelList` using the `ChannelList.Add` method.

The channel is appended to the end of the channel list.

Define another channel?

The driver sets the actual gain as closely as possible to the number specified. You can read back the exact gain after configuring the subsystem using the `Gain` property.

If inhibited, the values for the specified channel object are acquired, and then discarded.

Add another channel to the list?

Yes

No
Set up Common Subsystem Parameters

Set the channel type of the subsystem to SingleEnded or Differential using the **ChannelType** property within the appropriate subsystem class.

Set the data encoding of the subsystem to Binary or TwosComplement using the **Encoding** property within the appropriate subsystem class.

Set the voltage range of the subsystem using the **VoltageRange** property within the appropriate subsystem class.

Specify SingleEnded if you are using pseudo-differential channels.
Set Up Clocks

Using an internal clock?

Yes

Set the clock source to Internal using the `Clock.Source` property.

Set the frequency of the internal clock using the `Clock.Frequency` property.

No

Set the clock source to External using the `Clock.Source` property.

Specify a clock divider to apply to the external clock source using the `Clock.ExtClockDivider` property.

The driver sets the actual frequency as closely as possible to the number specified. You can read back the exact frequency after configuring the subsystem using the `Frequency` property.

The driver sets the actual clock divider as closely as possible to the number specified. You can read back the exact clock divider value after configuring the subsystem using the `ExtClockDivider` property.
Set Up Triggers

Set the start trigger type to one of the following values (if supported by your device) using the `AnalogInputSubsystem.Trigger.TriggerType` property: Software for a software (internal) trigger, TTLPos for an external TTL low-to-high trigger, DigitalEvent for a digital event trigger, TTLNeg for an external TTL high-to-low trigger, ThresholdPos for a positive-going threshold trigger, or ThresholdNeg for a negative-going threshold trigger.

Using a start trigger and reference trigger for pre-trigger/post-trigger operations?

Yes

Using threshold trigger for the start trigger?

Yes

Set the channel to use for the threshold trigger using the `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` property.

Set the level of the threshold trigger using the `AnalogInputSubsystem.Trigger.Level` property.

No

No

Set the reference trigger source to one of the following values using the `AnalogInputSubsystem.ReferenceTrigger.TriggerType` property: Software for a software (internal) trigger, TTLPos for an external TTL low-to-high trigger, DigitalEvent for a digital event trigger, TTLNeg for an external TTL high-to-low trigger, ThresholdPos for a positive-going threshold trigger, or ThresholdNeg for a negative-going threshold trigger. This trigger source stops pre-trigger acquisition, if in progress, and starts post-trigger acquisition.

Using threshold trigger for the reference trigger?

Yes

Set the channel to use for the threshold trigger using the `AnalogInputSubsystem.ReferenceTrigger.ThresholdTriggerChannel` property.

Set the level of the threshold trigger using the `AnalogInputSubsystem.ReferenceTrigger.Level` property.

No

Specify the number of samples to acquire after the reference trigger using the `AnalogInputSubsystem.ReferenceTrigger.PostTriggerScanCount` property.

Go to next page.
Set the post-trigger source to one of the following values (if supported by your device) using the `AnalogInputSubsystem.Trigger.TriggerType` property:

- Software for a software (internal) trigger,
- TTLPos for an external TTL low-to-high trigger,
- DigitalEvent for a digital event trigger,
- TTLNeg for an external TTL high-to-low trigger,
- ThresholdPos for a positive-going threshold trigger,
- ThresholdNeg for a negative-going threshold trigger.

This trigger source stops pre-trigger acquisition, if in progress, and starts post-trigger acquisition.

Using post-trigger or about-trigger mode without a reference trigger?

- Yes
  - If supported by your device, set the channel to use for the threshold trigger using the `AnalogInputSubsystem.Trigger.ThresholdTriggerChannel` property.
  - If supported by your device, set the level of the threshold trigger using the `AnalogInputSubsystem.Trigger.Level` property.

- No

Using a trigger to start analog output operations?

- Yes
  - Set the trigger source to one of the following values (if supported by your device) using the `AnalogOutputSubsystem.Trigger.TriggerType` property:
    - Software for a software (internal) trigger,
    - TTLPos for an external TTL low-to-high trigger,
    - DigitalEvent for a digital event trigger,
    - TTLNeg for an external TTL high-to-low trigger,
    - ThresholdPos for a positive-going threshold trigger,
    - ThresholdNeg for a negative-going threshold trigger.

  - If supported by your device, set the channel to use for the threshold trigger using the `AnalogOutputSubsystem.Trigger.ThresholdTriggerChannel` property.
  - If supported by your device, set the level of the threshold trigger using the `AnalogOutputSubsystem.Trigger.Level` property.

- No

Using threshold trigger?

- Yes
  - 
  - 

- No
Set Up Input Buffering

Use the `OlBuffer` constructor within the `OlBuffer` class to create an `OlBuffer` object and allocate an internal data buffer for use with an analog input subsystem.

Use the `AnalogInputSubsystem.BufferQueue.QueueBuffer` method to add the `OlBuffer` object to the queue for the analog input subsystem.

During this step, you also determine the size of the internal data buffer by specifying the number of samples in the buffer (each sample typically requires 2 bytes).

Continuous input operations require a minimum of two `OlBuffer` objects.
Set Up Output Buffering

Use the `OlBuffer` constructor within the `OlBuffer` class to create an `OlBuffer` object and allocate an internal data buffer for use with an analog output subsystem.

Create a user-specified array with the data to output.

Copy data from the user-specified array into the internal buffer of the `OlBuffer` object using one of the following methods: `OlBuffer.PutDataAsRaw` (to output raw counts) or `OlBuffer.PutDataAsVolts` (to output voltages).

Add the `OlBuffer` object to the queue for the analog output subsystem using the `AnalogOutputSubsystem.BufferQueue.QueueBuffer` method.

Allocate another buffer?

Set the buffer wrap mode of the analog output subsystem to True or False using the `AnalogOutputSubsystem.WrapSingleBuffer` property.

During this step, you also determine the size of the internal buffer by specifying the number of samples in the buffer (each sample typically requires 2 bytes).

Continuous output operations require two `OlBuffer` objects if `WrapSingleBuffer` is False (one if `WrapSingleBuffer` is True).

By default, `WrapSingleBuffer` is False. In this state, data is written from the allocated buffers continuously. As each buffer is emptied, a `BufferDone` event occurs. If no more buffers are available and queued to the subsystem, the operation stops.

If you set `WrapSingleBuffer` to True, the device driver continuously reuses the first buffer queued to the analog output subsystem. Data from a single output buffer is downloaded to the FIFO of the device (if supported by the device) and is written out starting from the first location of the buffer; when the end of the buffer is reached, the device starts outputting data from the first location of the buffer, and the process repeats.
Deal with Events and Buffers for Input Operations

PreTrigger BufferDoneEvent raised?

Yes

Use the PreTriggerBufferDoneHandler delegate to receive the BufferDoneEventArgs argument and handle the buffer.

No

OlBuffer ValidSamples > 0?

Yes

Declare a user-specified array of the appropriate type (determined by the method used next).

No

Copy the data from the internal buffer of an OlBuffer object to a user-specified array using
- OlBuffer.GetDataAsRawByte (converts to raw counts and copies into an array of bytes),
- OlBuffer.GetDataAsRawInt16 (converts two's complement data into raw counts when the resolution is 16 bits or less and copies into an array of signed, 16-bit integers),
- OlBuffer.GetDataAsRawUInt16 (converts binary data into raw counts when the resolution is 16 bits or less and copies into an array of unsigned 16-bit integers),
- OlBuffer.GetDataAsRawUInt32 (converts to raw counts when the resolution is more than 16-bits and copies into an array of unsigned 32-bit integers),
- OlBuffer.GetDataAsVolts (converts to voltage and copies into an array of floating-point values),
- OlBuffer.GetDataAsVoltsByte (converts to voltage and copies into an array of bytes),
- OlBuffer.GetDataAsSensor (converts to sensor values and copies into an array of floating-point values),
- OlBuffer.GetDataAsRpm (converts to RPM values and copies into an array of floating-point values).

Process the data in your program.

Add the OlBuffer object to the queue for the analog input subsystem using the BufferQueue.QueueBuffer method.

Go to the next page.
Use the BufferDoneHandler delegate to receive the BufferDoneEventArgs argument and handle the buffer.

Check if OIBuffer. ValidSamples > 0?
- Yes
  - Declare a user-specified array of the appropriate type (determined by the method used next).
- No

Copy the data from the internal buffer of an OIBuffer object to a user-specified array using
- OIBuffer.GetDataAsRawByte (converts to raw counts and copies into an array of bytes),
- OIBuffer.GetDataAsRawInt16 (converts two's complement data into raw counts when the resolution is 16 bits or less and copies into an array of signed, 16-bit integers),
- OIBuffer.GetDataAsRawUInt16 (converts binary data into raw counts when the resolution is 16 bits or less and copies into an array of unsigned 16-bit integers),
- OIBuffer.GetDataAsRawUInt32 (converts to raw counts when the resolution is more than 16 bits and copies into an array of unsigned 32-bit integers),
- OIBuffer.GetDataAsVolts (converts to voltage and copies into an array of floating-point values),
- OIBuffer.GetDataAsVoltsByte (converts to voltage and copies into an array of bytes),
- OIBuffer.GetDataAsSensor (converts to sensor values and copies into an array of floating-point values),
- OIBuffer.GetDataAsRpm (converts to RPMs and copies into an array of floating-point values).

Process the data in your program.

Add the OIBuffer object to the queue for the analog input subsystem using the AnalogInputSubsystem.BufferQueue.QueueBuffer method.

Go to the next page.
Chapter 6

Continued from previous page.

- **IOComplete Event raised?**
  - Yes: Use the `IOCompleteHandler` delegate to receive the `IOCompleteEventArgs` argument and handle the event.
  - No: Do nothing.

- **QueueDoneEvent raised?**
  - Yes: Use the `QueueDoneHandler` delegate to receive the `GeneralEventArgs` argument and handle the event.
  - No: Use the `QueueStoppedHandler` delegate to receive the `GeneralEventArgs` argument and handle the event.

- **QueueStopped Event raised?**
  - Yes: Use the `QueueStoppedHandler` delegate to receive the `GeneralEventArgs` argument and handle the event.
  - No: Use the `DriverRunTimeErrorEventHandler` delegate to receive the `DriverRunTimeErrorEventArgs` argument and handle the event.

- **DriverRunTime ErrorEvent raised?**
  - Yes: Use the `DriverRunTimeErrorEventHandler` delegate to receive the `DriverRunTimeErrorEventArgs` argument and handle the event.
  - No: Return to the top of page 420.
Deal with Events and Buffers for Output Operations

BufferDoneEvent raised?

Yes

Use the BufferDoneHandler delegate to receive the BufferDoneEventArgs argument and handle the buffer.

No

Refill buffers?

Yes

Create a user-specified array of the appropriate type with the data to output (determined by the method used next).

No

Copy data from a user-specified array into the internal buffer of the OlBuffer object using one of the following methods: OlBuffer.PutDataAsRaw (to output raw counts) or OlBuffer.PutDataAsVolts (to output voltages).

Add the OlBuffer object to the queue for the analog output subsystem using the AnalogOutputSubsystem.BufferQueue.QueueBuffer method.

Set the AnalogOutputSubsystem.WrapSingleBuffer property to True if you want the device driver to continuously reuse the first OlBuffer object queued to the subsystem.

Go to the next page.
Use the **IOCompleteHandler** delegate to receive the **IOCompleteEventArgs** argument and handle the event.

Note that in some cases, this event is raised well after the data is transferred from the buffer to the device (when **BufferDoneEvent** and **QueueDoneEvent** are raised).

Use the **QueueDoneHandler** delegate to receive the **GeneralEventArgs** argument and handle the event.

Use the **QueueStoppedHandler** delegate to receive the **GeneralEventArgs** argument and handle the event.

Use the **DriverRunTimeErrorEventHandler** delegate to receive the **DriverRunTimeErrorEventArgs** argument and handle the event.

Return to the top of page 423.
Stop the Operation

Stop in an orderly way?

Yes
Use the Stop method within the appropriate subsystem class to stop the operation after the current buffer has been completed.

No
The driver posts at least one BufferDoneEvent and QueueStoppedEvent events.

Reinitialize subsystem?

Yes
Use the Reset method within the appropriate subsystem class to stop the operation immediately without waiting for the current buffer to be completed, and reinitialize the subsystem to the default configuration.

No

Use the Abort method within the appropriate subsystem class to stop the operation immediately without waiting for the current buffer to be completed.
**Clean Up Single-Value I/O Operations**

- Release the subsystem connection to the hardware device using the `Dispose` method within the appropriate subsystem class.
- Release the device using the `Device.Dispose` method.

**Clean Up Buffered I/O Operations**

- Remove all `OlBuffer` objects queued to the subsystem and deallocate the associated internal buffers using the `BufferQueue.FreeAllQueueBuffers` method.
- For simultaneous operations only, clear the simultaneous start list using the `SimultaneousStart.Clear` method.
- Release the subsystem connection to the hardware device using the `Dispose` method within the appropriate subsystem class.
- Release the device using the `Device.Dispose` method.
Product Support
Should you experience problems using the DT-Open Layers for .NET Class Library, follow these steps:

1. Read all the appropriate sections of this manual, including any “Read This First” information.

2. Check for a README file on the Data Acquisition OMNI CD. If present, read this file for the latest installation and usage information.

3. Check that you have installed your hardware devices properly. For information, refer to the documentation supplied with your devices.

4. Check that you have installed the device drivers for your hardware devices properly. For information, refer to the documentation supplied with your devices.

5. Check that you have installed your software properly. For information, refer to page 21.

If you are still having problems, Data Translation’s Technical Support Department is available to provide technical assistance. To request technical support, go to our web site at http://www.datatranslation.com and click on the Support link.

When requesting technical support, be prepared to provide the following information:

- Your product serial number
- The hardware/software product you need help on
- The version of the CD you are using
- Your contract number, if applicable

If you are located outside the USA, contact your local distributor; see our web site (www.datatranslation.com) for the name and telephone number of your nearest distributor.
